INTRODUCTION

The **MOSEK** Optimization Suite 8.1.0.64 is a powerful software package capable of solving large-scale optimization problems of the following kind:

- linear,
- conic quadratic (also known as second-order cone),
- convex quadratic,
- semidefinite,
- and general convex.

Integer constrained variables are supported for all problem classes except for semidefinite and general convex problems. In order to obtain an overview of features in the **MOSEK** Optimization Suite consult the [product introduction](#) guide.

The most widespread class of optimization problems is *linear optimization problems*, where all relations are linear. The tremendous success of both applications and theory of linear optimization can be ascribed to the following factors:

- The required data are simple, i.e. just matrices and vectors.
- Convexity is guaranteed since the problem is convex by construction.
- Linear functions are trivially differentiable.
- There exist very efficient algorithms and software for solving linear problems.
- Duality properties for linear optimization are nice and simple.

Even if the linear optimization model is only an approximation to the true problem at hand, the advantages of linear optimization may outweigh the disadvantages. In some cases, however, the problem formulation is inherently nonlinear and a linear approximation is either intractable or inadequate. *Conic optimization* has proved to be a very expressive and powerful way to introduce nonlinearities, while preserving all the nice properties of linear optimization listed above.

The fundamental expression in linear optimization is a linear expression of the form

$$Ax - b \in \mathcal{K}$$

where $\mathcal{K} = \{y : y \geq 0\}$, i.e.,

$$\begin{aligned} Ax - b &= y, \\ y &\in \mathcal{K}. \end{aligned}$$

In conic optimization a wider class of convex sets \mathcal{K} is allowed, for example in 3 dimensions \mathcal{K} may correspond to an ice cream cone. The conic optimizer in **MOSEK** supports three structurally different types of cones \mathcal{K} , which allows a surprisingly large number of nonlinear relations to be modelled (as described in the [MOSEK modeling cookbook](#)), while preserving the nice algorithmic and theoretical properties of linear optimization.

1.1 Why the Fusion API for C++?

Fusion is an object oriented API specifically designed to build conic optimization models in a simple and expressive manner, using mainstream programming languages.

With focus on usability and compactness, it helps the user focus on modelling instead of coding.

Typically a conic optimization model in *Fusion* can be developed in a fraction of the time compared to using a low-level C API, but of course *Fusion* introduces a computational overhead compared to customized C code. In most cases, however, the overhead is small compared to the overall solution time, and we generally recommend that *Fusion* is used as a first step for building and verifying new models. Often, the final *Fusion* implementation will be directly suited for production code, and otherwise it readily provides a reference implementation for model verification. *Fusion* always yields readable and easily portable code.

The Fusion API for C++ provides access to Conic Optimization, including:

- Linear Optimization (LO)
- Conic Quadratic (Second-Order Cone) Optimization (CQO, SOCO)
- Semidefinite Optimization (SDO)

as well as to an auxiliary linear algebra library.

Convex Quadratic and Quadratically Constrained (QCQO) problems can be reformulated as Conic Quadratic problems and subsequently solved using *Fusion*. This is the recommended approach, as described in the **MOSEK** [the modeling cookbook](#) and this [whitepaper](#).

LICENSE AGREEMENT

Before using the **MOSEK** software, please read the license agreement available in the distribution at `<MSKHOME>/mosek/8/mosek-eula.pdf` or on the **MOSEK** website <https://mosek.com/products/license-agreement>.

MOSEK uses some third-party open-source libraries. Their license details follows.

zlib

MOSEK includes the *zlib* library obtained from the [zlib website](#). The license agreement for *zlib* is shown in [Listing 3.1](#).

Listing 3.1: *zlib* license.

INSTALLATION

In this section we discuss how to install and setup the **MOSEK** Fusion API for C++.

Important: Before running this **MOSEK** interface please make sure that you:

- Installed **MOSEK** correctly. Some operating systems require extra steps. See the [Installation guide](#) for instructions and common troubleshooting tips.
 - Set up a license. See the [Licensing guide](#) for instructions.
-

Compatibility

The Fusion API for C++ is compatible with the following compiler tool chains:

Platform	Supported compiler	Framework
Linux 64 bit	gcc (≥ 4.8)	glibc (≥ 2.2)
Mac OS 64 bit	Xcode (≥ 5)	MAC OS SDK (≥ 10.7)
Windows	Visual Studio (≥ 2015)	

In many cases older versions can also be used. In particular Fusion API for C++ requires a C++11 compliant compiler.

Locating Files

The files in Fusion API for C++ are organized as reported in [Table 4.1](#).

Table 4.1: Relevant files for the Fusion API for C++.

Relative Path	Description	Label
<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/h	Header files	<HEADERDIR>
<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/src/fusion_cxx	Source files	<SRCDIR>
<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/bin	Shared libraries	<LIBDIR>
<MSKHOME>/mosek/8/tools/examples/fusion/cxx	Examples	<EXDIR>
<MSKHOME>/mosek/8/tools/examples/fusion/data	Additional data	<MISCDIR>

where

- <MSKHOME> is the folder in which the **MOSEK** package has been installed,
- <PLATFORM> is the actual platform among those supported by **MOSEK**, i.e. win64x86, linux64x86 or osx64x86.

Manual compilation (all platforms)

This step is compulsory on Linux and Mac OS. The implementation of *Fusion* is distributed as C++ source code in `<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/src/fusion_cxx`. It can be compiled as follows:

1. Go to `<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/src/fusion_cxx`
2. Run `make install` (Linux, Mac OS) or `nmake install` (Windows).
3. If no error occurs, then the *Fusion* C++ API has been successfully compiled and the corresponding libraries have been copied to `<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/bin`.

Using a pre-compiled library (only Windows)

On Windows 64bit the users can skip the compilation step and use a pre-compiled library `fusion64_8_1.lib` available in `<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/bin`.

Setting up paths and linking

To compile and link a C++ application using *Fusion*, the user must set paths to header files, compiled *Fusion* libraries, and run-time dependencies must be resolved. Details vary depending on the operating system and compiler. See the `Makefile` included in the distribution under `<MSKHOME>/mosek/8/tools/examples/fusion/cxx` for a working example. Typically:

- Linux:

```
g++ -std=c++11 file.cc -o file -I<HEADERDIR> -L<LIBDIR> -Wl,-rpath-link,<LIBDIR> -Wl,-rpath=<LIBDIR> -lmosek64 -lfusion64
```

The shared libraries `libmosek64.so.8.1`, `libfusion64.so.8.1` must be available at runtime.

- Mac OS:

```
clang++ -std=c++11 -stdlib=libc++ file.cc -o file -I<HEADERDIR> -L<LIBDIR> -Wl,-headerpad,128 -lmosek64 -lfusion64
install_name_tool -change libmosek64.8.1.dylib <LIBDIR>/libmosek64.8.1.dylib file
install_name_tool -change libfusion64.8.1.dylib <LIBDIR>/libfusion64.8.1.dylib file
```

The shared libraries `libmosek64.8.1.dylib`, `libfusion64.8.1.dylib` must be available at runtime.

- Windows:

```
cl /I<HEADERDIR> file.cc /link /LIBPATH:<LIBDIR> fusion64_8_1.lib mosek64_8_1.lib
```

The shared library `mosek64_8_1.dll` must be available at runtime.

Importing the source code

Alternatively, the *Fusion* source code from `<MSKHOME>/mosek/8/tools/platform/<PLATFORM>/src/fusion_cxx` can be imported into any other project, or compiled into a stand-alone library by the user. This is especially useful if non-standard compiler options should be used.

4.1 Testing the installation and compiling examples

The example directory `<MSKHOME>/mosek/8/tools/examples/fusion/cxx` contains a makefile for use with `make` (Linux, Mac OS) or `nmake` (Windows).

To build the examples, open a shell (Linux, Mac OS) or a Developer Command Prompt and go to <EXDIR>. To compile all examples run the one of the commands

```
make all  
  
nmake all
```

depending on the operating system. To build only a single example, for instance `lo1.cc`, use one of the following:

```
make lo1  
  
nmake lo1.exe
```

4.2 Creating a Visual Studio Project

The following walk-through describes how to set up a 64bit *Fusion* project with Microsoft Visual Studio 2017. With another tools and setup configurations the steps should be similar.

- Create a Visual C++ project or open an existing project in Visual Studio.
- Go to **Project** → **Properties**.
- In the selection box **Configuration:** select **All Configurations**.
- If necessary go to **Configuration Manager** and change **Active Solution Platform** to x64.
- Under **Configuration Properties** → **C/C++** → **General** → **Additional Include Directories** add the full path to <HEADERDIR>.
- Under **Configuration Properties** → **Linker** → **Input** → **Additional Dependencies** add the full paths to the files `mosek64_8_1.lib` and `fusion64_8_1.lib`.
- Make sure that `mosek64_8_1.dll` is available in the DLL search path when executing the compiled code.

DESIGN OVERVIEW

Fusion is a result of many years of experience in conic optimization. It is a dedicated API for users who want to enjoy a simpler experience interfacing with the solver. This applies to users who regularly solve conic problems, and to new users who do not want to be too bothered with the technicalities of a low-level optimizer. *Fusion* is designed for fast and clean prototyping of conic problems without suffering excessive performance degradation.

Note that *Fusion* **is** an object-oriented framework for conic-optimization but it **is not** a general purpose modelling language. The main design principles of *Fusion* are:

- **Expressiveness:** we try to make it nice! Despite not being a modelling language, *Fusion* yields readable, easy to maintain code that closely resembles the mathematical formulation of the problem.
- **Seamlessly multi-language :** *Fusion* code can be ported across C++, Python, Java, .NET and MATLAB with only minimal adaptations to the syntax of each language.
- **What you write is what MOSEK gets:** A *Fusion* model is fed into the solver with (almost) no additional transformations.

Expressiveness

Suppose you have a conic quadratic optimization problem like the efficient frontier in portfolio optimization:

$$\begin{aligned} &\text{maximize} && \mu^T x - \alpha \gamma \\ &\text{subject to} && e^T x = w, \\ & && \gamma \geq \|G^T x\|, \\ & && x \geq 0. \end{aligned}$$

Its representation in *Fusion* is a direct translation of the mathematical model:

```
M->objective(ObjectiveSense::Maximize, Expr::sub(Expr::dot(mu, x), Expr::mul(alpha, gamma)));
M->constraint(Expr::sub(Expr::sum(x), w), Domain::equalsTo(0.0));
M->constraint(Expr::vstack(gamma, Expr::mul(Expr::transpose(G), x)), Domain::inQCone());
M->constraint(x, Domain::greaterThan(0.0));
```

Seamless multi-language API

Fusion can easily be ported across the five supported languages. All functionalities and naming conventions remain the same in all of them. This has some advantages:

- Simplifies code sharing between developers working in different languages.
- Improves code reusability.
- Simplifies the transition from R&D to production (for instance from fast-prototyping languages used in R&D to more efficient ones used for high performance).

Here is the same code snippet (creation of a variable in the model) in all five languages supported by *Fusion*. Careful code design can generate models with only the necessary syntactic differences between implementations.

```
auto x= M->variable("x", 3, Domain::greaterThan(0.0)); // C++
```

```
x = M.variable('x', 3, Domain.greaterThan(0.0)) # Python
```

```
Variable x = M.variable("x", 3, Domain.greaterThan(0.0)) // Java
```

```
Variable x = M.Variable("x", 3, Domain.GreaterThan(0.0)) // C#
```

```
x = M.variable('x', 3, Domain.greaterThan(0.0)) // MATLAB
```

What You Write is What MOSEK Gets

Fusion is not a modelling language. Instead it clearly defines the formulation the user must adhere to and only provides functionalities required for that formulation. An important upshot is that *Fusion* will not modify the problem provided by the user, except for introducing auxiliary variables required to fit the problem into the format of the low-level optimizer API. In other words, the problem that is actually solved is as close as possible to what the user writes.

For example, suppose the user defined a conic constraint

$$x_1 \geq \sqrt{(2x_2 - x_3)^2 + (4x_3)^2}.$$

Now the low-level API requires that all variables appearing in all conic constraints are different, and so *Fusion* will have to replace the conic constraint with

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & -1 \\ 0 & 0 & 4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = y,$$
$$y_1 \geq \sqrt{y_2^2 + y_3^2}.$$

Note, however, that to use the optimizer API directly the user would have to apply the same transformation! A similar situation happens when the user defines a number of linear constraints, which have to be arranged into a large linear constraint matrix A , and so on. So, in effect, the *Fusion* mechanism only automates operations that the user would have to carry out anyway (using pencil and paper, presumably). Otherwise the optimizer model is a direct copy of the *Fusion* model.

The main benefits of this approach are:

- The user knows what problem is actually being solved.
- Dual information is readily available for all variables and constraints.
- Only the necessary overhead.
- Better control over numerical stability.

CONIC MODELING

6.1 The model

A model built using *Fusion* is **always** a conic optimization problem and it is convex by definition. These problems can be succinctly characterized as

$$\begin{aligned} & \text{minimize} && c^T x \\ & \text{subject to} && Ax + b \in \mathcal{K} \end{aligned} \tag{6.1}$$

where \mathcal{K} is a product of the following basic types of cones:

- *linear*: \mathbb{R}^n , $\{x \in \mathbb{R}^n : x \leq u\}$, $\{x \in \mathbb{R}^n : l \leq x\}$, $\{x \in \mathbb{R}^n : l \leq x \leq u\}$, a point,
- *quadratic*: $\mathcal{Q}^n = \{x \in \mathbb{R}^n : x_1 \geq \sqrt{x_2^2 + \dots + x_n^2}\}$,
- *rotated quadratic*: $\mathcal{Q}_r^n = \{x \in \mathbb{R}^n : 2x_1x_2 \geq x_3^2 + \dots + x_n^2, x_1, x_2 \geq 0\}$,
- *semidefinite*:: $\mathcal{S}_+^n = \{X \in \mathbb{R}^{n \times n} : X \text{ is symmetric positive semidefinite}\}$.

The main thing about a *Fusion* model is that it can be specified in a convenient way without explicitly constructing the representation (6.1). Instead the user has access to *variables* which are used to construct *linear operators* that appear in *constraints*. The cone types described above are the domains of those constraints. A *Fusion* model can potentially contain many different building blocks of that kind. To facilitate manipulations with a large number of variables *Fusion* defines various *logical views* of parts of the model.

This section briefly summarizes the constructions and techniques available in *Fusion*. See [Sec. 7](#) for a basic tutorial and [Sec. 10](#) for more advanced case studies. This section is only an introduction: detailed specification of the methods and classes mentioned here can be found in the [API reference](#).

A *Fusion* model is represented by the class *Model* and created by a simple construction

```
Model::t M = new Model();    auto _M = finally([&](){ M->dispose(); });
```

The model object is the user's interface to the optimization problem, used in particular for

- formulating the problem by defining variables, constraints and objective,
- solving the problem and retrieving the solution status and solutions,
- interacting with the solver: setting up parameters, registering for callbacks, performing I/O, obtaining detailed information from the optimizer etc.
- memory management.

Almost all elements of the model: variables, constraints and the model itself can be constructed with or without names. If used, the names for each type of object must be unique. Choosing a good naming convention can make the problem more readable when dumped to a file. Most *Fusion* components also support some degree of pretty printing (*toString* method).

6.2 Variables

Continuous variables can be scalars, vectors or higher-dimensional arrays. They are added to the model with the method `Model.variable` which returns a representing object of type `Variable`. The shape of a variable (number of dimensions and length in each dimension) has to be specified at creation. Optionally a variable may be created in a restricted domain (by default variables are unbounded, that is in \mathbb{R}). For instance, to declare a variable $x \in \mathbb{R}_+^n$ we could write

```
auto x = M->variable("x", n, Domain::greaterThan(0.));
```

A multi-dimensional variable is declared by specifying an array with all dimension sizes. Here is an $n \times n$ variable:

```
auto x = M->variable( new_array_ptr<int,1>({n,n}), Domain::unbounded() );
```

The specification of dimensions can also be part of the domain, as in this declaration of a symmetric positive semidefinite variable of dimension n :

```
auto v = M->variable(Domain::inPSDCone(n));
```

Integer variables are specified with an additional domain modifier. To add an integer variable $z \in [1, 10]$ we write

```
auto z = M->variable("z", Domain::integral(Domain::inRange(1.,10.)) );
```

The function `Domain.binary` is a shorthand for binary variables often appearing in combinatorial problems:

```
auto y = M->variable("y", Domain::binary());
```

Integrality requirement can be switched on and off using the methods `Variable.makeInteger` and `Variable.makeContinuous`.

The `Variable` object provides the primal (`Variable.level`) and dual (`Variable.dual`) solution values of the variable after optimization, and it enters in the construction of linear expressions involving the variable.

6.3 Linear algebra

Linear expressions are constructed combining *variables* and *matrices* by linear operators. The result is an object that represents the linear expression itself. *Fusion* only allows for those combinations of operators and arguments that yield linear functions of the variables. Expressions have shapes and dimensions in the same fashion as variables. For instance, if $x \in \mathbb{R}^n$ and $A \in \mathbb{R}^{m \times n}$, then Ax is a vector expression of length m . Note, however, that the internal size of Ax is mn , because each entry is a linear combination for which m coefficients have to be stored.

Expressions are concrete implementations of the virtual interface `Expression`. In typical situations, however, all operations on expressions can be performed using the static methods and factory methods of the class `Expr`.

Table 6.1: Linear Operators

Method	Description
<i>Expr.add</i>	Element-wise addition of two matrices
<i>Expr.sub</i>	Element-wise subtraction of two matrices
<i>Expr.mul</i>	Matrix or matrix-scalar multiplication
<i>Expr.neg</i>	Sign inversion
<i>Expr.outer</i>	Vector outer-product
<i>Expr.dot</i>	Dot product
<i>Expr.sum</i>	Sum over a given dimension
<i>Expr.mulDiag</i>	Sum over the diagonal of a matrix which is the result of a matrix multiplication
<i>Expr.constTerm</i>	Return a <i>constant term</i>

Operations on expressions must adhere to the rules of matrix algebra regarding dimensions; otherwise a *DimensionError* exception will be thrown.

Expression can be composed, nested and used as building blocks in new expressions. For instance $Ax + By$ can be implemented as:

```
Expr::add( Expr::mul(A,x), Expr::mul(B,y) );
```

For operations involving multiple variables and expressions the users should consider list-based methods. For instance, a clean way to write $x + y + z + w$ would be:

```
Expr::add( new_array_ptr<Variable::t,1>({x, y, z, w}));
```

Note that a single variable (object of class *Variable*) can also be used as an expression. Once constructed, expressions are immutable.

6.4 Constraints and objective

Constraints are declared within an optimization model using the method *Model.constraint*. Every constraint in *Fusion* has the form

Expression belongs to a *Domain*.

Objects of type *Domain* correspond roughly to the types of convex cones \mathcal{K} mentioned at the beginning of this section. For instance, the following set of linear constraints

$$\begin{array}{rclcl} x_1 & + & 2x_2 & & = 0 \\ & & & + & x_3 & = 0 \\ x_1 & & & & = 0 \end{array} \quad (6.2)$$

could be declared as

```
auto A = new_array_ptr<double,2>({
    { 1.0, 2.0, 0.0},
    { 0.0, 1.0, 1.0},
    { 1.0, 0.0, 0.0 } });

auto x = M->variable("x",3,Domain::unbounded());
auto c = M->constraint( Expr::mul(A,x), Domain::equalsTo(0.0));
```

Note that the scalar domain *Domain.equalsTo* consisting of a single point 0 scales up to the dimension of the expression and applies to all its elements. This allows many constraints to be comfortably expressed in a vectorized form. See also Sec. 6.7.

The *Constraint* object provides the dual (*Constraint.dual*) value of the constraint after optimization and the primal value of the constraint expression (*Constraint.level*).

The typical domains used to specify constraints are listed below. Note that they can also be used directly at variable creation, whenever that makes sense.

	Type	Domain
Linear	equality	<i>Domain.equalsTo</i>
	inequality \leq	<i>Domain.lessThan</i>
	inequality \geq	<i>Domain.greaterThan</i>
	two-sided bound	<i>Domain.inRange</i>
Conic Quadratic	quadratic cone	<i>Domain.inQCone</i>
	rotated quadratic cone	<i>Domain.inRotatedQCone</i>
Semidefinite	PSD matrix	<i>Domain.inPSDCone</i>
Integral	Integers in domain D	<i>Domain.integral</i> (D)
	$\{0, 1\}$	<i>Domain.binary</i>

Having discussed variables and constraints we can finish by defining the optimization objective with *Model.objective*. The objective function is a scalar expression and the objective sense is specified by the enumeration *ObjectiveSense* as either *minimize* or *maximize*. The typical linear objective function $c^T x$ can be declared as

```
M->objective( ObjectiveSense::Minimize, Expr::mul(c,x) );
```

6.5 Matrices

At some point it becomes necessary to specify linear expressions such as Ax where A is a (large) constant data matrix. Such coefficient matrices can be represented in dense or sparse format. Dense matrices can always be represented using the standard data structures for arrays and two-dimensional arrays built into the language. Alternatively, or when sparsity can be exploited, matrices can be constructed as objects of the class *Matrix*. This can have some advantages: a more generic code that can be ported across platforms and can be used with *both* dense and sparse matrices without modifications.

Dense matrices are constructed with a variant of the static factory method *Matrix.dense*. The values of all entries must be specified all at once and the resulting matrix is immutable. For example the matrix

$$A = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{bmatrix}$$

can be defined with:

```
auto A = new_array_ptr<double,2>({ {1,2,3,4}, {5,6,7,8} });
auto Ad= Matrix::dense(A);
```

or from a flattened representation:

```
auto Af = new_array_ptr<double,1>({ 1,2,3,4,5,6,7,8 });
auto Aff= Matrix::dense(2,4,Af);
```

Sparse matrices are constructed with a variant of the static factory method *Matrix.sparse*. This is both speed- and memory-efficient when the matrix has few nonzero entries. A matrix A in sparse format is given by a list of triples (i, j, v) , each defining one entry: $A_{i,j} = v$. The order does not matter. The entries not in the list are assumed to be 0. For example, take the matrix

$$A = \begin{bmatrix} 1.0 & 0.0 & 0.0 & 2.0 \\ 0.0 & 3.0 & 0.0 & 4.0 \end{bmatrix}.$$

Assuming we number rows and columns from 0, the corresponding list of triplets is:

$$A = \{(0, 0, 1.0), (0, 3, 2.0), (1, 1, 3.0), (1, 3, 4.0)\}$$

The *Fusion* definition would be:

```

auto rows = new_array_ptr<int,1>({ 0, 0, 1, 1 });
auto cols = new_array_ptr<int,1>({ 0, 3, 1, 3 });
auto values = new_array_ptr<double,1>({ 1.0, 2.0, 3.0, 4.0 });

auto ms = Matrix::sparse(rows->size(), cols->size(), rows, cols, values);

```

The *Matrix* class provides more standard constructions such as the identity matrix, a constant value matrix, block diagonal matrices etc.

6.6 Stacking and views

Fusion provides a way to construct logical views of parts of existing expressions or combinations of existing expressions. They are still represented by objects of type *Variable* or *Expression* that refer to the original ones. This can be useful in some scenarios:

- retrieving only the values of a few variables, and ignoring the remaining auxiliary ones,
- stacking vectors or matrices to perform various matrix operations,
- bundling a number of similar constraints into one; see [Sec. 6.7](#),
- adding constraints between parts of the same variable, etc.

All these operations do not require *new* variables or expressions, but just lightweight *logical views*. In what follows we will concentrate on expressions; the same techniques are available for variables. These techniques will be familiar to the users of numerical tools such as Matlab or NumPy.

Picking and slicing

Expression.pick picks a subset of entries from a variable or expression. Special cases of picking are *Expression.index*, which picks just one scalar entry and *Expression.slice* which picks a *slice*, that is restricts each dimension to a subinterval. Slicing is a frequently used operation.

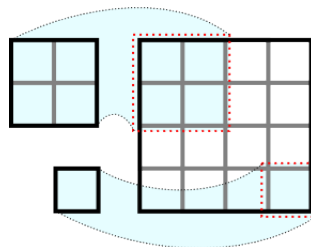

Fig. 6.1: Two dimensional slicing.

Both displayed regions are slices of the two-dimensional 4×4 expression, which can be selected as follows:

```

auto Axs1 = Ax->slice( new_array_ptr<int,1>({0,0}), new_array_ptr<int,1>({2,2}) );
auto Axs2 = Ax->index( new_array_ptr<int,1>({3,3}) );

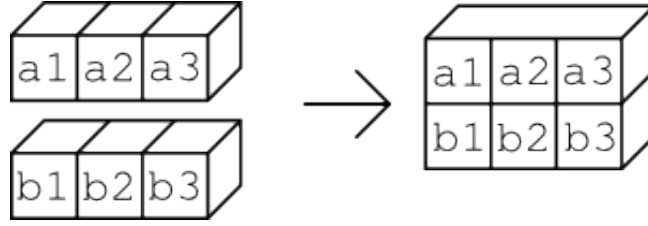

```

Reshaping

Expressions can be *reshaped* creating a view with the same number of coordinates arranged in a different way. A particular example of this operation is *flattening*, which converts any multi-dimensional expression into a one-dimensional vector.

Stacking

Stacking refers to the concatenation of expressions to form a new larger one. For example, the next figure depicts the *vertical stacking* of two vectors of shape 1×3 resulting in a matrix of shape 2×3 .

```
auto c = Expr::vstack(new_array_ptr<Expression::t,1>({a,b}));
```

Vertical stacking ([Expr.vstack](#)) of expressions of shapes $d_1 \times d_2$ and $d'_1 \times d_2$ has shape $(d_1 + d'_1) \times d_2$. Similarly, *horizontal stacking* ([Expr.hstack](#)) of expressions of shapes $d_1 \times d_2$ and $d_1 \times d'_2$ has shape $d_1 \times (d_2 + d'_2)$. *Fusion* supports also more general versions of stacking for multi-dimensional variables, as described in [Expr.stack](#). A special case of stacking is *repetition* ([Expr.repeat](#)), equivalent to stacking copies of the same expression.

6.7 Vectorization

Using *Fusion* one can compactly express sequences of similar constraints. For example, if we want to express

$$Ax_i = b_i, \quad i = 1, \dots, n$$

we can think of $x_i \in \mathbb{R}^m, b_i \in \mathbb{R}^k$ as the columns of two matrices $X = [x_1, \dots, x_n] \in \mathbb{R}^{m \times n}$, $B = [b_1, \dots, b_n] \in \mathbb{R}^{k \times n}$, and write simply

$$AX - B = 0.$$

```
auto X = Var::hstack( new_array_ptr<Variable::t,1>({xi(0), xi(1), xi(2), xi(3)}) );
auto B = Expr::hstack( new_array_ptr<Expression::t,1>({bi(0), bi(1), bi(2), bi(3)}) );

M->constraint(Expr::sub(Expr::mul(A, X), B), Domain::equalsTo(0.0));
```

In this example the domain [Domain.equalsTo](#) scales to apply to all the entries of the expression.

Another powerful case of vectorization and scaling domains is the ability to define a sequence of conic constraints in one go. Suppose we want to find an upper bound on the 2-norm of a sequence of vectors, that is we want to express

$$t \geq \|y_i\|, \quad i = 1, \dots, n$$

Suppose that the vectors y_i are arranged in the rows of a matrix Y . Then we can simply write:

```
auto t = M->variable();

M->constraint(Expr::hstack(Var::vrepeat(t, n), Y), Domain::inQCone());
```

Here, again, the conic domain [Domain.inQCone](#) is by default applied to each row of the matrix separately, yielding the desired constraints in a loop-free way (the i -th row is (t, y_i)). The direction along which conic constraints are created within multi-dimensional expressions can be changed with [Domain.axis](#).

We recommend vectorizing the code whenever possible. It is not only more elegant and portable but also more efficient — loops are eliminated and the number of *Fusion* API calls is reduced.

6.8 Reoptimization

Between optimizations the user can modify the model in two ways:

- Add new constraints with `Model.constraint`. This is useful for solving a sequence of optimization problems with more and more restrictions on the feasible set. See for example [Sec. 10.9](#).
- Replace the objective with a new one. This is particularly useful when solving a sequence of problems with the same data but different objectives, for instance in multi-objective optimization. For simplicity, suppose we want to minimize $f(x) = \gamma x + \beta y$, for varying choices of $\gamma > 0$. Then we could write:

```
double gamma[] = {0., 0.5, 1.0};           // Choices for gamma
double beta = 2.0;
auto x= M->variable("x", 1, Domain::greaterThan(0.));
auto y= M->variable("y", 1, Domain::greaterThan(0.));
auto beta_y = Expr::mul(beta,y);

for(auto g : gamma)
{
    M->objective( ObjectiveSense::Minimize, Expr::add(Expr::mul(g,x), beta_y) );
    M->solve();
}
```

- Add a new expression to an existing constraint (`Constraint.add`).

Otherwise all *Fusion* objects are immutable.

OPTIMIZATION TUTORIALS

In this section we demonstrate how to set up basic types of optimization problems. Each short tutorial contains a working example of formulating problems, defining variables and constraints and retrieving solutions.

7.1 Linear Optimization

The simplest optimization problem is a purely linear problem. A *linear optimization problem* is a problem of the following form:

Minimize or maximize the objective function

$$\sum_{j=0}^{n-1} c_j x_j + c^f$$

subject to the linear constraints

$$l_k^c \leq \sum_{j=0}^{n-1} a_{kj} x_j \leq u_k^c, \quad k = 0, \dots, m-1,$$

and the bounds

$$l_j^x \leq x_j \leq u_j^x, \quad j = 0, \dots, n-1.$$

The problem description consists of the following elements:

- m and n — the number of constraints and variables, respectively,
- x — the variable vector of length n ,
- c — the coefficient vector of length n

$$c = \begin{bmatrix} c_0 \\ \vdots \\ c_{n-1} \end{bmatrix},$$

- c^f — fixed term in the objective,
- A — an $m \times n$ matrix of coefficients

$$A = \begin{bmatrix} a_{0,0} & \cdots & a_{0,(n-1)} \\ \vdots & \cdots & \vdots \\ a_{(m-1),0} & \cdots & a_{(m-1),(n-1)} \end{bmatrix},$$

- l^c and u^c — the lower and upper bounds on constraints,
- l^x and u^x — the lower and upper bounds on variables.

Please note that we are using 0 as the first index: x_0 is the first element in variable vector x .

The *Fusion* user does not need to specify all of the above elements explicitly — they will be assembled from the *Fusion* model.

7.1.1 Example LO1

The following is an example of a small linear optimization problem:

$$\begin{aligned} &\text{maximize} && 3x_0 + 1x_1 + 5x_2 + 1x_3 \\ &\text{subject to} && 3x_0 + 1x_1 + 2x_2 &= 30, \\ & && 2x_0 + 1x_1 + 3x_2 + 1x_3 &\geq 15, \\ & && & 2x_1 &+ 3x_3 &\leq 25, \end{aligned} \tag{7.1}$$

under the bounds

$$\begin{aligned} 0 &\leq x_0 \leq \infty, \\ 0 &\leq x_1 \leq 10, \\ 0 &\leq x_2 \leq \infty, \\ 0 &\leq x_3 \leq \infty. \end{aligned}$$

We start our implementation in *Fusion* importing the relevant modules, i.e.

```
#include "fusion.h"
using namespace mosek::fusion;
using namespace monty;
```

Next we declare an optimization model creating an instance of the *Model* class:

```
Model::t M = new Model("lo1"); auto _M = finally([&]() { M->dispose(); });
```

For this simple problem we are going to enter all the linear coefficients directly:

```
auto A1 = new_array_ptr<double, 1>({ 3.0, 1.0, 2.0, 0.0 });
auto A2 = new_array_ptr<double, 1>({ 2.0, 1.0, 3.0, 1.0 });
auto A3 = new_array_ptr<double, 1>({ 0.0, 2.0, 0.0, 3.0 });
auto c = new_array_ptr<double, 1>({ 3.0, 1.0, 5.0, 1.0 });
```

The variables appearing in problem (7.1) can be declared as one 4-dimensional variable:

```
Variable::t x = M->variable("x", 4, Domain::greaterThan(0.0));
```

At this point we already have variables with bounds $0 \leq x_i \leq \infty$, because the domain is applied element-wise to the entries of the variable vector. Next, we impose the upper bound on x_1 :

```
M->constraint(x->index(1), Domain::lessThan(10.0));
```

The linear constraints can now be entered one by one using the dot product of our variable with a coefficient vector:

```
M->constraint("c1", Expr::dot(A1, x), Domain::equalsTo(30.0));
M->constraint("c2", Expr::dot(A2, x), Domain::greaterThan(15.0));
M->constraint("c3", Expr::dot(A3, x), Domain::lessThan(25.0));
```

We end the definition of our optimization model setting the objective function in the same way:

```
M->objective("obj", ObjectiveSense::Maximize, Expr::dot(c, x));
```

Finally, we only need to call the *Model.solve* method:

```
M->solve();
```

The solution values can be attained with the method `Variable.level`.

```
auto sol = x->level();
std::cout << "[x0,x1,x2,x3] = " << (*sol) << "\n";
```

Listing 7.1: *Fusion* implementation of model (7.1).

```
#include <iostream>
#include "fusion.h"
using namespace mosek::fusion;
using namespace monty;

int main(int argc, char ** argv)
{
    auto A1 = new_array_ptr<double>, 1>({ 3.0, 1.0, 2.0, 0.0 });
    auto A2 = new_array_ptr<double>, 1>({ 2.0, 1.0, 3.0, 1.0 });
    auto A3 = new_array_ptr<double>, 1>({ 0.0, 2.0, 0.0, 3.0 });
    auto c = new_array_ptr<double>, 1>({ 3.0, 1.0, 5.0, 1.0 });

    // Create a model with the name 'lo1'
    Model::t M = new Model("lo1"); auto _M = finally([&]() { M->dispose(); });

    M->setLogHandler([ = ](const std::string & msg) { std::cout << msg << std::flush; });

    // Create variable 'x' of length 4
    Variable::t x = M->variable("x", 4, Domain::greaterThan(0.0));

    // Create constraints
    M->constraint(x->index(1), Domain::lessThan(10.0));
    M->constraint("c1", Expr::dot(A1, x), Domain::equalsTo(30.0));
    M->constraint("c2", Expr::dot(A2, x), Domain::greaterThan(15.0));
    M->constraint("c3", Expr::dot(A3, x), Domain::lessThan(25.0));

    // Set the objective function to (c~t * x)
    M->objective("obj", ObjectiveSense::Maximize, Expr::dot(c, x));

    // Solve the problem
    M->solve();

    // Get the solution values
    auto sol = x->level();
    std::cout << "[x0,x1,x2,x3] = " << (*sol) << "\n";
}
```

7.2 Conic Quadratic Optimization

Conic optimization is a generalization of linear optimization, allowing constraints of the type

$$x^t \in \mathcal{K}_t,$$

where x^t is a subset of the problem variables and \mathcal{K}_t is a convex cone. Since the set \mathbb{R}^n of real numbers is also a convex cone, we can simply write a compound conic constraint $x \in \mathcal{K}$ where $\mathcal{K} = \mathcal{K}_1 \times \cdots \times \mathcal{K}_l$ is a product of smaller cones and x is the full problem variable.

MOSEK can solve conic quadratic optimization problems of the form

$$\begin{aligned} & \text{minimize} && c^T x + c^f \\ & \text{subject to} && \begin{aligned} l^c &\leq Ax \leq u^c, \\ l^x &\leq x \leq u^x, \\ x &\in \mathcal{K}, \end{aligned} \end{aligned}$$

where the domain restriction, $x \in \mathcal{K}$, implies that all variables are partitioned into convex cones

$$x = (x^0, x^1, \dots, x^{p-1}), \quad \text{with } x^t \in \mathcal{K}_t \subseteq \mathbb{R}^{n_t}.$$

For convenience, a user defining a conic quadratic problem only needs to specify subsets of variables x^t belonging to quadratic cones. These are:

- Quadratic cone:

$$\mathcal{Q}^n = \left\{ x \in \mathbb{R}^n : x_0 \geq \sqrt{\sum_{j=1}^{n-1} x_j^2} \right\}.$$

- Rotated quadratic cone:

$$\mathcal{Q}_r^n = \left\{ x \in \mathbb{R}^n : 2x_0x_1 \geq \sum_{j=2}^{n-1} x_j^2, \quad x_0 \geq 0, \quad x_1 \geq 0 \right\}.$$

For example, the following constraint:

$$(x_4, x_0, x_2) \in \mathcal{Q}^3$$

describes a convex cone in \mathbb{R}^3 given by the inequality:

$$x_4 \geq \sqrt{x_0^2 + x_2^2}.$$

In *Fusion* the coordinates of a cone are not restricted to single variables. They can be arbitrary linear expressions, and an auxiliary variable will be substituted by *Fusion* in a way transparent to the user.

7.2.1 Example CQO1

Consider the following conic quadratic problem which involves some linear constraints, a quadratic cone and a rotated quadratic cone.

$$\begin{aligned} & \text{minimize} && y_1 + y_2 + y_3 \\ & \text{subject to} && \begin{aligned} x_1 + x_2 + 2.0x_3 &= 1.0, \\ x_1, x_2, x_3 &\geq 0.0, \\ (y_1, x_1, x_2) &\in \mathcal{Q}^3, \\ (y_2, y_3, x_3) &\in \mathcal{Q}_r^3. \end{aligned} \end{aligned} \tag{7.2}$$

We start by creating the optimization model:

```
Model::t M = new Model("cqo1"); auto _M = finally([&] () { M->dispose(); });
```

We then define variables x and y . Two logical variables (aliases) $z1$ and $z2$ are introduced to model the quadratic cones. These are not new variables, but map onto parts of x and y for the sake of convenience.

```
Variable::t x = M->variable("x", 3, Domain::greaterThan(0.0));
Variable::t y = M->variable("y", 3, Domain::unbounded());

// Create the aliases
//   z1 = [ y[0], x[0], x[1] ]
// and z2 = [ y[1], y[2], x[2] ]
Variable::t z1 = Var::vstack(y->index(0), x->slice(0, 2));
Variable::t z2 = Var::vstack(y->slice(1, 3), x->index(2));
```

The linear constraint is defined using the dot product:

```
// Create the constraint
//      x[0] + x[1] + 2.0 x[2] = 1.0
auto aval = new_array_ptr<double, 1>({1.0, 1.0, 2.0});
M->constraint("lc", Expr::dot(aval, x), Domain::equalsTo(1.0));
```

The conic constraints are defined using the logical views *z1* and *z2* created previously. Note that this is a basic way of defining conic constraints, and that in practice they would have more complicated structure.

```
// Create the constraints
//      z1 belongs to C_3
//      z2 belongs to K_3
// where C_3 and K_3 are respectively the quadratic and
// rotated quadratic cone of size 3, i.e.
//      z1[0] >= sqrt(z1[1]^2 + z1[2]^2)
// and 2.0 z2[0] z2[1] >= z2[2]^2
Constraint::t qc1 = M->constraint("qc1", z1, Domain::inQCone());
Constraint::t qc2 = M->constraint("qc2", z2, Domain::inRotatedQCone());
```

We only need the objective function:

```
// Set the objective function to (y[0] + y[1] + y[2])
M->objective("obj", ObjectiveSense::Minimize, Expr::sum(y));
```

Calling the *Model.solve* method invokes the solver:

```
M->solve();
```

The primal and dual solution values can be retrieved using *Variable.level*, *Constraint.level* and *Variable.dual*, *Constraint.dual*, respectively:

```
// Get the linear solution values
ndarray<double, 1> xlvl = *(x->level());
ndarray<double, 1> ylvl = *(y->level());
```

```
// Get conic solution of qc1
ndarray<double, 1> qc1lvl = *(qc1->level());
ndarray<double, 1> qc1dl = *(qc1->dual());
```

Listing 7.2: *Fusion* implementation of model (7.2).

```
#include <iostream>
#include "fusion.h"

using namespace mosek::fusion;
using namespace monty;

int main(int argc, char ** argv)
{
    Model::t M = new Model("cqo1"); auto _M = finally([&]() { M->dispose(); });

    Variable::t x = M->variable("x", 3, Domain::greaterThan(0.0));
    Variable::t y = M->variable("y", 3, Domain::unbounded());

    // Create the aliases
    //      z1 = [ y[0], x[0], x[1] ]
    // and z2 = [ y[1], y[2], x[2] ]
    Variable::t z1 = Var::vstack(y->index(0), x->slice(0, 2));
    Variable::t z2 = Var::vstack(y->slice(1, 3), x->index(2));

    // Create the constraint
```

```

//      x[0] + x[1] + 2.0 x[2] = 1.0
auto aval = new_array_ptr<double>, 1>({1.0, 1.0, 2.0});
M->constraint("lc", Expr::dot(aval, x), Domain::equalsTo(1.0));

// Create the constraints
//      z1 belongs to C_3
//      z2 belongs to K_3
// where C_3 and K_3 are respectively the quadratic and
// rotated quadratic cone of size 3, i.e.
//      z1[0] >= sqrt(z1[1]^2 + z1[2]^2)
// and 2.0 z2[0] z2[1] >= z2[2]^2
Constraint::t qc1 = M->constraint("qc1", z1, Domain::inQCone());
Constraint::t qc2 = M->constraint("qc2", z2, Domain::inRotatedQCone());

// Set the objective function to (y[0] + y[1] + y[2])
M->objective("obj", ObjectiveSense::Minimize, Expr::sum(y));

// Solve the problem
M->solve();

// Get the linear solution values
ndarray<double>, 1> xlv1 = *(x->level());
ndarray<double>, 1> ylv1 = *(y->level());
// Get conic solution of qc1
ndarray<double>, 1> qc1lv1 = *(qc1->level());
ndarray<double>, 1> qc1dl = *(qc1->dual());

std::cout << "x1,x2,x3 = " << xlv1 << std::endl;
std::cout << "y1,y2,y3 = " << ylv1 << std::endl;
std::cout << "qc1 levels = " << qc1lv1 << std::endl;
std::cout << "qc1 dual conic var levels = " << qc1dl << std::endl;
}

```

7.3 Semidefinite Optimization

Semidefinite optimization is a generalization of conic quadratic optimization, allowing the use of matrix variables belonging to the convex cone of positive semidefinite matrices

$$\mathcal{S}_+^r = \{X \in \mathcal{S}^r : z^T X z \geq 0, \quad \forall z \in \mathbb{R}^r\},$$

where \mathcal{S}^r is the set of $r \times r$ real-valued symmetric matrices.

MOSEK can solve semidefinite optimization problems of the form

$$\begin{aligned}
& \text{minimize} && \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle \overline{C}_j, \overline{X}_j \rangle + c^f \\
& \text{subject to} && \begin{aligned} l_i^c &\leq \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle \overline{A}_{ij}, \overline{X}_j \rangle &\leq u_i^c, & i = 0, \dots, m-1, \\ l_j^x &\leq x_j &\leq u_j^x, & j = 0, \dots, n-1, \\ & x \in \mathcal{K}, \overline{X}_j \in \mathcal{S}_+^{r_j}, & & j = 0, \dots, p-1 \end{aligned}
\end{aligned}$$

where the problem has p symmetric positive semidefinite variables $\overline{X}_j \in \mathcal{S}_+^{r_j}$ of dimension r_j with symmetric coefficient matrices $\overline{C}_j \in \mathcal{S}^{r_j}$ and $\overline{A}_{ij} \in \mathcal{S}^{r_j}$. We use standard notation for the matrix inner product, i.e., for $A, B \in \mathbb{R}^{m \times n}$ we have

$$\langle A, B \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} A_{ij} B_{ij}.$$

In *Fusion* the user can enter the linear expressions in a more convenient way, without having to cast the problem exactly in the above form.

7.3.1 Example SDO1

We consider the simple optimization problem with semidefinite and conic quadratic constraints:

$$\begin{aligned}
 & \text{minimize} && \left\langle \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, \bar{X} \right\rangle + x_0 \\
 & \text{subject to} && \left\langle \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \bar{X} \right\rangle + x_0 &= 1, \\
 & && \left\langle \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \bar{X} \right\rangle + x_1 + x_2 &= 1/2, \\
 & && x_0 \geq \sqrt{x_1^2 + x_2^2}, & \bar{X} \succeq 0,
 \end{aligned} \tag{7.3}$$

The problem description contains a 3-dimensional symmetric semidefinite variable which can be written explicitly as:

$$\bar{X} = \begin{bmatrix} \bar{X}_{00} & \bar{X}_{10} & \bar{X}_{20} \\ \bar{X}_{10} & \bar{X}_{11} & \bar{X}_{21} \\ \bar{X}_{20} & \bar{X}_{21} & \bar{X}_{22} \end{bmatrix} \in \mathcal{S}_+^3,$$

and a conic quadratic variable $(x_0, x_1, x_2) \in \mathcal{Q}^3$. The objective is to minimize

$$2(\bar{X}_{00} + \bar{X}_{10} + \bar{X}_{11} + \bar{X}_{21} + \bar{X}_{22}) + x_0,$$

subject to the two linear constraints

$$\begin{aligned}
 \bar{X}_{00} + \bar{X}_{11} + \bar{X}_{22} + x_0 &= 1, \\
 \bar{X}_{00} + \bar{X}_{11} + \bar{X}_{22} + 2(\bar{X}_{10} + \bar{X}_{20} + \bar{X}_{21}) + x_1 + x_2 &= 1/2.
 \end{aligned}$$

Our implementation in *Fusion* begins with creating a new model:

```
Model::t M = new Model("sdo1"); auto _M = finally([&]() { M->dispose(); });
```

We create a symmetric semidefinite variable \bar{X} and another variable representing x . For simplicity we immediately declare that x belongs to a quadratic cone

```
Variable::t X = M->variable("X", Domain::inPSDCone(3));
Variable::t x = M->variable("x", Domain::inQCone(3));
```

In this elementary example we are going to create an explicit matrix representation of the problem

$$\bar{C} = \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, \quad \bar{A}_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \bar{A}_2 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}.$$

and use it in the model via the dot product operation $\langle \cdot, \cdot \rangle$ which applies to matrices as well as to vectors. This way we create each of the linear constraints and the objective as one expression.

```
// Objective
M->objective(ObjectiveSense::Minimize, Expr::add(Expr::dot(C, X), x->index(0)));

// Constraints
M->constraint("c1", Expr::add(Expr::dot(A1, X), x->index(0)), Domain::equalsTo(1.0));
M->constraint("c2", Expr::add(Expr::dot(A2, X), Expr::sum(x->slice(1, 3))),
↳Domain::equalsTo(0.5));
```

Now it remains to solve the problem with *Model.solve*.

Listing 7.3: *Fusion* implementation of problem (7.3).

```

#include <iostream>
#include "fusion.h"

using namespace mosek::fusion;
using namespace monty;

int main(int argc, char ** argv)
{
    Model::t M = new Model("sdo1"); auto _M = finally([&]() { M->dispose(); });

    // Setting up the variables
    Variable::t X = M->variable("X", Domain::inPSDCone(3));
    Variable::t x = M->variable("x", Domain::inQCone(3));

    // Setting up the constant coefficient matrices
    Matrix::t C = Matrix::dense ( new_array_ptr<double, 2>({{2., 1., 0.}, {1., 2., 1.}, {0., 1.,
↪ 2.}}));
    Matrix::t A1 = Matrix::eye(3);
    Matrix::t A2 = Matrix::ones(3, 3);

    // Objective
    M->objective(ObjectiveSense::Minimize, Expr::add(Expr::dot(C, X), x->index(0)));

    // Constraints
    M->constraint("c1", Expr::add(Expr::dot(A1, X), x->index(0)), Domain::equalsTo(1.0));
    M->constraint("c2", Expr::add(Expr::dot(A2, X), Expr::sum(x->slice(1, 3))),
↪ Domain::equalsTo(0.5));

    M->solve();

    std::cout << "Solution : " << std::endl;
    std::cout << " X = " << *(X->level()) << std::endl;
    std::cout << " x = " << *(x->level()) << std::endl;

    return 0;
}

```

7.4 Integer Optimization

An optimization problem where one or more of the variables are constrained to integer values is called a (mixed) integer optimization problem. **MOSEK** supports integer variables in combination with linear and conic quadratic problems. See the previous tutorials for an introduction to how to model these types of problems.

7.4.1 Example MILO1

We use the example

$$\begin{aligned}
 &\text{maximize} && x_0 + 0.64x_1 \\
 &\text{subject to} && 50x_0 + 31x_1 \leq 250, \\
 & && 3x_0 - 2x_1 \geq -4, \\
 & && x_0, x_1 \geq 0 \quad \text{and integer}
 \end{aligned} \tag{7.4}$$

to demonstrate how to set up and solve a problem with integer variables. It has the structure of a linear optimization problem (see Sec. 7.1) except for integrality constraints on the variables. Therefore, only the specification of the integer constraints requires something new compared to the linear optimization problem discussed previously.

First, the integrality constraints are imposed by modifying any existing domain with *Domain.integral*:

```
Variable::t x = M->variable("x", 2, Domain::integral(Domain::greaterThan(0.0)));
```

Next, the example demonstrates how to set various useful parameters of the mixed-integer optimizer. See Sec. 13 for details.

```
// Set max solution time
M->setSolverParam("mioMaxTime", 60.0);
// Set max relative gap (to its default value)
M->setSolverParam("mioTolRelGap", 1e-4);
// Set max absolute gap (to its default value)
M->setSolverParam("mioTolAbsGap", 0.0);
```

The complete source for the example is listed in Listing 7.4.

Listing 7.4: How to solve problem (7.4).

```
#include <iostream>
#include <iomanip>
#include "fusion.h"

using namespace mosek::fusion;
using namespace monty;

int main(int argc, char ** argv)
{
    auto a1 = new_array_ptr<double>, 1>({ 50.0, 31.0 });
    auto a2 = new_array_ptr<double>, 1>({ 3.0, -2.0 });
    auto c = new_array_ptr<double>, 1>({ 1.0, 0.64 });

    Model::t M = new Model("milo1"); auto _M = finally([&]() { M->dispose(); });
    Variable::t x = M->variable("x", 2, Domain::integral(Domain::greaterThan(0.0)));

    // Create the constraints
    //      50.0 x[0] + 31.0 x[1] <= 250.0
    //      3.0 x[0] - 2.0 x[1] >= -4.0
    M->constraint("c1", Expr::dot(a1, x), Domain::lessThan(250.0));
    M->constraint("c2", Expr::dot(a2, x), Domain::greaterThan(-4.0));

    // Set max solution time
    M->setSolverParam("mioMaxTime", 60.0);
    // Set max relative gap (to its default value)
    M->setSolverParam("mioTolRelGap", 1e-4);
    // Set max absolute gap (to its default value)
    M->setSolverParam("mioTolAbsGap", 0.0);

    // Set the objective function to (c^T * x)
    M->objective("obj", ObjectiveSense::Maximize, Expr::dot(c, x));

    // Solve the problem
    M->solve();

    // Get the solution values
    auto sol = x->level();
    std::cout << std::setiosflags(std::ios::scientific) << std::setprecision(2)
        << "x1 = " << (*sol)[0] << std::endl
        << "x2 = " << (*sol)[1] << std::endl
        << "MIP rel gap = " << M->getSolverDoubleInfo("mioObjRelGap") << " (" << M->
        << getSolverDoubleInfo("mioObjAbsGap") << ")" << std::endl;
}
```

7.4.2 Specifying an initial solution

Solution time can often be reduced by providing an initial solution for the solver. It is not necessary to specify the whole solution. By setting the `mioConstructSol` parameter to `"on"` and inputting values for the integer variables only, **MOSEK** will be forced to compute the remaining continuous variable values. If the specified integer solution is infeasible or incomplete, **MOSEK** will simply ignore it.

We concentrate on a simple example below.

$$\begin{aligned} &\text{maximize} && 7x_0 + 10x_1 + x_2 + 5x_3 \\ &\text{subject to} && x_0 + x_1 + x_2 + x_3 \leq 2.5 \\ & && x_0, x_1, x_2 \in \mathbb{Z} \\ & && x_0, x_1, x_2, x_3 \geq 0 \end{aligned} \tag{7.5}$$

We initialize the mixed-integer optimizer with a feasible starting point $(x_0, x_1, x_2, x_3) = (0, 2, 0, 0)$ using the method `Variable.setLevel`:

Listing 7.5: *Fusion* implementation of problem (7.5) specifying an initial solution.

```
auto init_sol = new_array_ptr<double, 1>({ 0.0, 2.0, 0.0, 0.0 });
x->setLevel( init_sol );
```

The complete code is not very different from the first example and is available for download as `mioinitsol.cc`. For more details about this process see [Sec. 13](#). An more advanced application of `Variable.setLevel` is presented in the case study on [Multiprocessor scheduling](#).

7.5 Problem Modification and Reoptimization

Often one might want to solve not just a single optimization problem, but a sequence of problems, each differing only slightly from the previous one. This section demonstrates how to modify and re-optimize an existing problem. The example we study is a simple production planning model.

Problem modifications regarding variables, cones, objective function and constraints can be grouped in categories:

- adding constraints and variables,
- modifying existing constraints.

Adding new variables and constraints is very easy. Modifications to existing constraints are more cumbersome, and the user should consider whether it is not worth rebuilding the model from scratch in such case. The amount of work required by *Fusion* to update the optimizer task may outweigh the potential gains.

Depending on the type of modification, **MOSEK** may be able to optimize the modified problem more efficiently exploiting the information and internal state from the previous execution. After optimization, the solution is always stored internally, and is available before next optimization. The former optimal solution may be still feasible, but no longer optimal; or it may remain optimal if the modification of the objective function was small.

In general, **MOSEK** exploits dual information and availability of an optimal basis from the previous execution. The simplex optimizer is well suited for exploiting an existing primal or dual feasible solution. Restarting capabilities for interior-point methods are still not as reliable and effective as those for the simplex algorithm. More information can be found in Chapter 10 of the book [\[Chv83\]](#).

Parameter settings (see [Sec. 8.4](#)) can also be changed between optimizations.

7.5.1 Example: Production Planning

A company manufactures three types of products. Suppose the stages of manufacturing can be split into three parts: Assembly, Polishing and Packing. In the table below we show the time required for each

stage as well as the profit associated with each product.

Product no.	Assembly (minutes)	Polishing (minutes)	Packing (minutes)	Profit (\$)
0	2	3	2	1.50
1	4	2	3	2.50
2	3	3	2	3.00

With the current resources available, the company has 100,000 minutes of assembly time, 50,000 minutes of polishing time and 60,000 minutes of packing time available per year. We want to know how many items of each product the company should produce each year in order to maximize profit?

Denoting the number of items of each type by x_0, x_1 and x_2 , this problem can be formulated as a linear optimization problem:

$$\begin{aligned}
 &\text{maximize} && 1.5x_0 + 2.5x_1 + 3.0x_2 \\
 &\text{subject to} && 2x_0 + 4x_1 + 3x_2 \leq 100000, \\
 &&& 3x_0 + 2x_1 + 3x_2 \leq 50000, \\
 &&& 2x_0 + 3x_1 + 2x_2 \leq 60000,
 \end{aligned} \tag{7.6}$$

and

$$x_0, x_1, x_2 \geq 0.$$

Code in [Listing 7.6](#) loads and solves this problem.

Listing 7.6: Setting up and solving problem (7.6)

```

auto c = new_array_ptr<double>, 1>({ 1.5, 2.5, 3.0 });
auto A = new_array_ptr<double>, 2>({ {2, 4, 3},
                                     {3, 2, 3},
                                     {2, 3, 2} });

auto b = new_array_ptr<double>, 1>({ 100000.0, 50000.0, 60000.0 });
int numvar = 3;
int numcon = 3;

// Create a model and input data
Model::t M = new Model(); auto M_ = monty::finally([&]() { M->dispose(); });

auto x = M->variable(numvar, Domain::greaterThan(0.0));
auto con = M->constraint(Expr::mul(A, x), Domain::lessThan(b));
M->objective(ObjectiveSense::Maximize, Expr::dot(c, x));
// Solve the problem
M->solve();

```

7.5.2 Changing the Linear Constraint Matrix

Suppose we want to change the time required for assembly of product 0 to 3 minutes. This corresponds to setting $a_{0,0} = 3$. Now the *Constraint* provides the method *Constraint.add*, which sums the constraint expression with another expression and updates the constraint expression. In our case the update we need is $1 \cdot x_0$ (since $2 + 1 = 3$).

```
con->index(0)->add(x->index(0));
```

The problem now has the form:

$$\begin{aligned}
 &\text{maximize} && 1.5x_0 + 2.5x_1 + 3.0x_2 \\
 &\text{subject to} && 3x_0 + 4x_1 + 3x_2 \leq 100000, \\
 &&& 3x_0 + 2x_1 + 3x_2 \leq 50000, \\
 &&& 2x_0 + 3x_1 + 2x_2 \leq 60000,
 \end{aligned} \tag{7.7}$$

and

$$x_0, x_1, x_2 \geq 0.$$

After this operation we can reoptimize the problem.

7.5.3 Appending Variables

We now want to add a new product with the following data:

Product no.	Assembly (minutes)	Polishing (minutes)	Packing (minutes)	Profit (\$)
3	4	0	1	1.00

This corresponds to creating a new variable x_3 , appending a new column to the A matrix and setting a new term in the objective. We do this in [Listing 7.7](#)

Listing 7.7: How to add a new variable (column)

```

/***** Add a new variable *****/
// Create a variable and a compound view of all variables
auto x3 = M->variable(Domain::greaterThan(0.0));
auto xNew = Var::vstack(x, x3);
// Add to the existing constraint
con->add(Expr::mul(x3, new_array_ptr<double, 1>({ 4, 0, 1 })));
// Change the objective to include x3
M->objective(ObjectiveSense::Maximize, Expr::dot(new_array_ptr<double, 1>({1.5,2.5,3.0,1.0}),
↪ xNew));

```

After this operation the new problem is:

$$\begin{aligned}
 &\text{maximize} && 1.5x_0 + 2.5x_1 + 3.0x_2 + 1.0x_3 \\
 &\text{subject to} && 3x_0 + 4x_1 + 3x_2 + 4x_3 \leq 100000, \\
 & && 3x_0 + 2x_1 + 3x_2 \leq 50000, \\
 & && 2x_0 + 3x_1 + 2x_2 + 1x_3 \leq 60000,
 \end{aligned} \tag{7.8}$$

and

$$x_0, x_1, x_2, x_3 \geq 0.$$

7.5.4 Appending Constraints

Now suppose we want to add a new stage to the production process called *Quality control* for which 30000 minutes are available. The time requirement for this stage is shown below:

Product no.	Quality control (minutes)
0	1
1	2
2	1
3	1

This corresponds to adding the constraint

$$x_0 + 2x_1 + x_2 + x_3 \leq 30000$$

to the problem. This is done as follows.

Listing 7.8: Adding a new constraint.

```
/****** Add a new constraint *****/  
M->constraint(Expr::dot(xNew, new_array_ptr<double, 1>({1, 2, 1, 1})),  
↳Domain::lessThan(30000.0));
```

Again, we can continue with re-optimizing the modified problem.

For a more in-depth treatment see the following sections:

- *Case studies* for more advanced and complicated optimization examples.
- *Problem Formulation and Solutions* for formal mathematical formulations of problems **MOSEK** can solve, dual problems and infeasibility certificates.

SOLVER INTERACTION TUTORIALS

In this section we cover the interaction with the solver.

8.1 Accessing the solution

This section contains important information about the status of the solver and the status of the solution, which must be checked in order to properly interpret the results of the optimization.

8.1.1 Solver termination

If an error occurs during optimization then the method `Model.solve` will throw an exception of type `OptimizeError`. The method `FusionRuntimeException.toString` will produce a description of the error, if available. More about exceptions in [Sec. 8.2](#).

If a runtime error causes the program to crash during optimization, the first debugging step is to enable logging and check the log output. See [Sec. 8.3](#).

If the optimization completes successfully, the next step is to check the solution status, as explained below.

8.1.2 Available solutions

MOSEK uses three kinds of optimizers and provides three types of solutions:

- basic solution (BAS, from the simplex optimizer),
- interior-point solution (ITR, from the interior-point optimizer),
- integer solution (ITG, from the mixed-integer optimizer).

Under standard parameters settings the following solutions will be available for various problem types:

Table 8.1: Types of solutions available from **MOSEK**

	Simplex optimizer	Interior-point optimizer	Mixed-integer optimizer
Linear problem	<code>SolutionType.Basic</code>	<code>SolutionType.Interior</code>	
Conic (nonlinear) problem		<code>SolutionType.Interior</code>	
Problem with integer variables			<code>SolutionType.Integer</code>

For linear problems the user can force a specific optimizer choice making only one of the two solutions available. For example, if the user disables basis identification, then only the interior point solution will

be available for a linear problem. Numerical issues may cause one of the solutions to be unknown even if another one is feasible.

Not all components of a solution are always available. For example, there is no dual solution for integer problems.

The user will always need to specify which solution should be accessed.

Moreover, the user may be oblivious to the actual solution type by always referring to `SolutionType.Default`, which will automatically select the best available solution, if there is more than one. Moreover, the method `Model.selectedSolution` can be used to fix one solution type for all future references.

8.1.3 Problem and solution status

Assuming that the optimization terminated without errors, the next important step is to check the problem and solution status. There is one for every type of solution, as explained above.

Problem status

Problem status (`ProblemStatus`, retrieved with `Model.getProblemStatus`) determines whether the problem is certified as feasible. Its values can roughly be divided into the following broad categories:

- **feasible** — the problem is feasible. For continuous problems and when the solver is run with default parameters, the feasibility status should ideally be `ProblemStatus.PrimalAndDualFeasible`.
- **primal/dual infeasible** — the problem is infeasible or unbounded or a combination of those. The exact problem status will indicate the type of infeasibility.
- **unknown** — the solver was unable to reach a conclusion, most likely due to numerical issues.

Solution status

Solution status (`SolutionStatus`, retrieved with `Model.getPrimalSolutionStatus` and `Model.getDualSolutionStatus`) provides the information about what the solution values actually contain. The most important broad categories of values are:

- **optimal** (`SolutionStatus.Optimal`) — the solution values are feasible and optimal.
- **near optimal** (`SolutionStatus.NearOptimal`) — the solution values are feasible and they were certified to be at least nearly optimal up to some accuracy.
- **certificate** — the solution is in fact a certificate of infeasibility (primal or dual, depending on the solution).
- **unknown/undefined** — the solver could not solve the problem or this type of solution is not available for a given problem.

The solution status determines the action to be taken. For example, in some cases a suboptimal solution may still be valuable and deserve attention. It is the user's responsibility to check the status and quality of the solution.

Typical status reports

Here are the most typical optimization outcomes described in terms of the problem and solution statuses. Note that these do not cover all possible situations that can occur.

Table 8.2: Continuous problems (solution status for `SolutionType.Interior` or `SolutionType.Basic`)

Outcome	Problem status	Solution status (primal)	Solution status (dual)
Optimal	<i>ProblemStatus.PrimalAndDualFeasible</i>	<i>SolutionStatus.Optimal</i>	<i>SolutionStatus.Optimal</i>
Primal infeasible	<i>ProblemStatus.PrimalInfeasible</i>	<i>SolutionStatus.Unknown</i>	<i>SolutionStatus.Certificate</i>
Dual infeasible	<i>ProblemStatus.DualInfeasible</i>	<i>SolutionStatus.Certificate</i>	<i>SolutionStatus.Unknown</i>
Uncertain (stall, numerical issues, etc.)	<i>ProblemStatus.Unknown</i>	<i>SolutionStatus.Unknown</i>	<i>SolutionStatus.Unknown</i>

Table 8.3: Integer problems (solution status for `SolutionType.Integer`, others undefined)

Outcome	Problem status	Solution status (primal)	Solution status (dual)
Integer optimal	<i>ProblemStatus.PrimalFeasible</i>	<i>SolutionStatus.Optimal</i>	<i>SolutionStatus.Unknown</i>
Infeasible	<i>ProblemStatus.PrimalInfeasible</i>	<i>SolutionStatus.Unknown</i>	<i>SolutionStatus.Unknown</i>
Integer feasible point	<i>ProblemStatus.PrimalFeasible</i>	<i>SolutionStatus.Feasible</i>	<i>SolutionStatus.Unknown</i>
No conclusion	<i>ProblemStatus.Unknown</i>	<i>SolutionStatus.Unknown</i>	<i>SolutionStatus.Unknown</i>

8.1.4 Retrieving solution values

After the meaning and quality of the solution (or certificate) have been established, we can query for the actual numerical values. They can be accessed with methods such as:

- *Model.primalObjValue*, *Model.dualObjValue* — the primal and dual objective value.
- *Variable.level* — solution values for the variables.
- *Constraint.level* — values of the constraint expressions in the current solution.
- *Constraint.dual*, *Variable.dual* — dual values.

Remark

By default only *at least near optimal* solutions are returned. An attempt to access a solution with a weaker status will result in an exception. This can be changed by choosing another level of *acceptable* solutions with the method *Model.acceptedSolutionStatus*. In particular, this method must be called to enable retrieving suboptimal solutions and infeasibility certificates. For instance, one could write

```
M->acceptedSolutionStatus(AccSolutionStatus::Feasible);
```

The current setting of acceptable solutions can be checked with *Model.getAcceptedSolutionStatus*.

8.2 Errors and exceptions

Exceptions

Almost every method in Fusion API for C++ can throw an exception informing that the requested operation was not performed correctly, and indicating the type of error that occurred. This is the case in situations such as for instance:

- incompatible dimensions in a linear expression,
- defining an invalid value for a parameter,
- accessing an undefined solution,
- repeating a variable name, etc.

It is therefore a good idea to catch exceptions of type *FusionException* and its specific subclasses. The one case where it is *extremely important* to do so is when *Model.solve* is invoked. We will say more about this in [Sec. 8.1](#).

The exception contains a short diagnostic message. They can be accessed as in the following example.

```
try {
    M->setSolverParam("intpntCoTolRelGap", 1.01);
} catch (mosek::fusion::ParameterError& e) {
    std::cout << "Error: " << e.toString() << "\n";
}
```

It will produce as output:

```
Error: Invalid value for parameter (intpntCoTolRelGap)
```

Optimizer errors and warnings

The optimizer may also produce warning messages. They indicate non-critical but important events, that will not prevent solver execution, but may be an indication that something in the optimization problem might be improved. Warning messages are normally printed to a log stream (see [Sec. 8.3](#)). A typical warning is, for example:

```
MOSEK warning 53: A numerically large upper bound value 6.6e+09 is specified for constraint
↪ 'C69200' (46020).
```

8.3 Input/Output

The *Model* class is also a proxy for input/output operations related to an optimization model.

8.3.1 Stream logging

By default the solver runs silently and does not produce any output to the console or otherwise. However, the log output can be redirected to a user-defined output stream or stream callback function. The log output is analogous to the one produced by the command-line version of **MOSEK**.

To redirect all log messages use the method *Model.setLogHandler*. For instance, we can use the standard output:

```
M->setLogHandler([=](const std::string & msg) { std::cout << msg << std::flush; } );
```

A log stream can be detached by passing NULL.

8.3.2 Log verbosity

The logging verbosity can be controlled by setting the relevant parameters, as for instance

- `log`,
- `logIntpnt`,
- `logMio`,
- `logCutSecondOpt`,
- `logSim`, and
- `logSimMinor`.

Each parameter controls the output level of a specific functionality or algorithm. The main switch is `log` which affect the whole output. The actual log level for a specific functionality is determined as the minimum between `log` and the relevant parameter. For instance, the log level for the output produce by the interior-point algorithm is tuned by the `logIntpnt`; the actual log level is defined by the minimum between `log` and `logIntpnt`.

Tuning the solver verbosity may require adjusting several parameters. It must be noticed that verbose logging is supposed to be of interest during debugging and tuning. When output is no more of interest, the user can easily disable it globally with `log`. Larger values of `log` do not necessarily result in increased output.

By default **MOSEK** will reduce the amount of log information after the first optimization on a given problem. To get full log output on subsequent re-optimizations set `logCutSecondOpt` to zero.

8.3.3 Saving a problem to a file

An optimization model defined in *Fusion* can be dumped to a file using the method `Model.writeTask`. The file format will be determined from the filename's extension. Supported formats are listed in [Sec. 15](#) together with a table of problem types supported by each.

For instance the problem can be written to an MPS file with

```
M->writeTask("dump.mps");
```

All formats can be compressed with `gzip` by appending the `.gz` extension, for example

```
M->writeTask("dump.mps.gz");
```

Some remarks:

- The problem is written to the file as it is represented in the underlying *optimizer task*, that is including auxiliary variables introduced by *Fusion* if necessary.
- Unnamed variables are given generic names. It is therefore recommended to use meaningful variable names if the problem file is meant to be human-readable.
- The `task` format is **MOSEK**'s native file format which contains all the problem data as well as solver settings.

8.3.4 Reading a problem from a file

It is not possible to read a file saved with `Model.writeTask` back into *Fusion* because the structure of the high-level optimization model is not saved. However, such problem files can be solved with the command-line tool or read by the low-level Optimizer API if necessary. See the documentation of those interfaces for details.

8.3.5 Pretty printing

Most *Fusion* objects (variables, matrices, expressions, constraints) provide a `toString()` method which returns a plain text string representation of the object. This can be useful for inspecting and debugging the contents of small models. In general, the string will contain

- object type,
- size and dimension,
- the contents of the object, usually using a sparse representation.

For example, consider the element-wise product of the identity matrix with a square variable:

```
auto x = M->variable("x", new_array_ptr<int,1>({4,4}), Domain::unbounded());
auto ee = Expr::mulElm(Matrix::eye(4), x);
std::cout<< ee->toString() << std::endl;
```

This will be formatted as

```
Expr(ndim=(4,4),
  [ ([0 0]) -> + 1.0 X[0,0],
    ([1 1]) -> + 1.0 X[1,1],
    ([2 2]) -> + 1.0 X[2,2],
    ([3 3]) -> + 1.0 X[3,3] ])
```

As expected, only the nonzeros are printed.

8.4 Setting solver parameters

MOSEK comes with a large number of parameters that allows the user to tune the behavior of the optimizer. The typical settings which can be changed with solver parameters include:

- choice of the optimizer for linear problems,
- choice of primal/dual solver,
- turning presolve on/off,
- turning heuristics in the mixed-integer optimizer on/off,
- level of multi-threading,
- feasibility tolerances,
- solver termination criteria,
- behaviour of the license manager,

and more. All parameters have default settings which will be suitable for most typical users.

The API reference contains:

- *Full list of parameters*
- *List of parameters grouped by topic*

Setting parameters

Each parameter is identified by a unique string name and it can accept either integers, floating point values or symbolic strings. Parameters are set using the method `Model.setSolverParam`. *Fusion* will try to convert the given argument to the exact expected type, and will raise an exception if that fails.

Some parameters accept only symbolic strings from a fixed set of values. The set of accepted values for every parameter is provided in the API reference.

For example, the following piece of code sets up parameters which choose and tune the interior point optimizer before solving a problem.

Listing 8.1: Parameter setting example.

```
// Set log level (integer parameter)
M->setSolverParam("log", 1);
// Select interior-point optimizer... (parameter with symbolic string values)
M->setSolverParam("optimizer", "intpnt");
// ... without basis identification (parameter with symbolic string values)
M->setSolverParam("intpntBasis", "never");
// Set relative gap tolerance (double parameter)
M->setSolverParam("intpntCoTolRelGap", 1.0e-7);

// The same in a different way
M->setSolverParam("intpntCoTolRelGap", "1.0e-7");

// Incorrect value
try {
    M->setSolverParam("intpntCoTolRelGap", -1);
}
catch (mosek::fusion::ParameterError) {
    std::cout << "Wrong parameter value\n";
}
```

8.5 Retrieving information items

After the optimization the user has access to the solution as well as to a report containing a large amount of additional *information items*. For example, one can obtain information about:

- **timing**: total optimization time, time spent in various optimizer subroutines, number of iterations, etc.
- **solution quality**: feasibility measures, solution norms, constraint and bound violations, etc.
- **problem structure**: counts of variables of different types, constraints, nonzeros, etc.
- **integer optimizer**: integrality gap, objective bound, number of cuts, etc.

and more. Information items are numerical values of integer, long integer or double type. The full list can be found in the API reference:

- *Double information items*
- *Integer information items*
- *Long information items*

Certain information items make sense, and are made available, also *during* the optimization process. They can be accessed from a callback function, see [Sec. 8.7](#) for details.

Remark

For efficiency reasons, not all information items are automatically computed after optimization. To force all information items to be updated use the parameter *autoUpdateSolInfo*.

Retrieving the values

Values of information items are fetched using one of the methods

- *Model.getSolverDoubleInfo* for a double information item,

- `Model.getSolverIntInfo` for an integer information item,
- `Model.getSolverLIntInfo` for a long integer information item.

Each information item is identified by a unique name. The example below reads two pieces of data from the solver: total optimization time and the number of interior-point iterations.

Listing 8.2: Information items example.

```
double tm = M->getSolverDoubleInfo("optimizerTime");
int it = M->getSolverIntInfo("intpntIter");

std::cout << "Time: " << tm << "\nIterations: " << it << "\n";
```

8.6 Stopping the solver

The `Model` provides the method `Model.breakSolver` that notifies the solver that it must stop as soon as possible. The solver will not terminate momentarily, as it only periodically checks for such notifications. In any case, it will stop as soon as possible. The typical usage pattern of this method would be:

- build the optimization model `M`,
- create a separate thread in which `M` will run,
- break the solver by calling `Model.breakSolver` from the main thread.

Warnings and comments:

- It is recommended to use the solver parameters to set or modify standard built-in termination criteria (such as maximal running time, solution tolerances etc.). See [Sec. 8.4](#).
- More complicated user-defined termination criteria can be implemented within a callback function. See [Sec. 8.7](#).
- The state of the solver and solution after termination may be undefined.
- This operation is very language dependent and particular care must be taken to avoid stalling or other undesired side effects.

8.6.1 Example: Setting a Time Limit

For the purpose of the tutorial we will implement a busy-waiting breaker with the time limit as a termination criterion. Note that in practice it would be better just to set the parameter `optimizerMaxTime`.

Suppose we built a model `M` that is known to run for quite a long time (in the accompanying example code we create a particular integer program). Then we could create a new thread solving the model:

```
bool alive = true;
std::thread T(std::function<void(void)>([&]() { M->solve(); alive = false; }) );
```

In the main thread we are going to check if a time limit has elapsed. After calling `Model.breakSolver` we should wait for the solver thread to actually return. Altogether this scenario can be implemented as follows:

Listing 8.3: Stopping solver execution.

```
bool alive = true;
std::thread T(std::function<void(void)>([&]() { M->solve(); alive = false; }) );

time_t T0 = time(NULL);
while (true)
{
    if (time(NULL) - T0 > timeout)
```

```

{
    std::cout << "Solver terminated due to timeout!\n";
    M->breakSolver();
    T.join();
    break;
}
if (! alive)
{
    std::cout << "Solver terminated before anything happened!\n";
    T.join();
    break;
}
}

```

8.7 Progress and data callback

Callbacks are a very useful mechanism that allow the caller to track the progress of the **MOSEK** optimizer. A callback function provided by the user is regularly called during the optimization and can be used to

- obtain a customized log of the solver execution,
- collect information for debugging purposes or
- ask the solver to terminate.

Fusion API for C++ has the following callback mechanisms:

- **progress callback**, which provides only the basic status of the solver.
- **data callback**, which provides the solver status and a complete set of information items that describe the progress of the optimizer in detail.

Warning

The callbacks functions *must not* invoke any functions of the solver, environment or task. Otherwise the state of the solver and its outcome are undefined.

8.7.1 Data callback

In the data callback **MOSEK** passes a callback code and values of all information items to a user-defined function. The callback function is called, in particular, at the beginning of each iteration of the interior-point optimizer. For the simplex optimizers *logSimFreq* controls how frequently the call-back is called. Note that the callback is done quite frequently, which can lead to degraded performance. If the information items are not required, the simpler progress callback may be a better choice.

The data callback is set by calling the method *Model.setDataCallbackHandler*.

The callback function should have the following signature

```

int callback(MSKcallbackcodee   caller,
             const double*      douinf,
             const int32_t*      intinf,
             const int64_t*      lintinf)

```

Arguments:

- **caller** - the status of the optimizer.
- **douinf** - values of double information items.

- `intinf` - values of integer information items.
- `lintinf` - values of long information items.

Return value: Non-zero return value of the callback function indicates that the optimizer should be terminated.

8.7.2 Progress callback

In the progress callback **MOSEK** provides a single code indicating the current stage of the optimization process.

The callback is set by calling the method `Model.setCallbackHandler`.

The callback function should have the following signature

```
int progress(MSKcallbackcodee caller)
```

Arguments:

- `caller` - the status of the optimizer.

Return value: Non-zero return value of the callback function indicates that the optimizer should be terminated.

8.7.3 Working example: Data callback

The following example defines a data callback function that prints out some of the information items. It interrupts the solver after a certain time limit.

Note that the time limit refers to time spent in the solver and does not include setting up the model in *Fusion*.

Listing 8.4: An example of a data callback function.

```
static int MSKAPI usercallback( MSKcallbackcodee caller,
                                const double * douinf,
                                const int32_t * intinf,
                                const int64_t * lintinf,
                                Model::t mod,
                                const double maxtime)
{
    switch ( caller )
    {
    case MSK_CALLBACK_BEGIN_INTPNT:
        std::cerr << "Starting interior-point optimizer\n";
        break;
    case MSK_CALLBACK_INTPNT:
        std::cerr << "Iterations: " << intinf[MSK_IINF_INTPNT_ITER];
        std::cerr << " (" << douinf[MSK_DINF_OPTIMIZER_TIME] << "/";
        std::cerr << douinf[MSK_DINF_INTPNT_TIME] << ")s. \n";
        std::cerr << "Primal obj.: " << douinf[MSK_DINF_INTPNT_PRIMAL_OBJ];
        std::cerr << " Dual obj.: " << douinf[MSK_DINF_INTPNT_DUAL_OBJ] << std::endl;
        break;
    case MSK_CALLBACK_END_INTPNT:
        std::cerr << "Interior-point optimizer finished.\n";
        break;
    case MSK_CALLBACK_BEGIN_PRIMAL_SIMPLEX:
        std::cerr << "Primal simplex optimizer started.\n";
        break;
    case MSK_CALLBACK_UPDATE_PRIMAL_SIMPLEX:
        std::cerr << "Iterations: " << intinf[MSK_IINF_SIM_PRIMAL_ITER];
        std::cerr << " Elapsed time: " << douinf[MSK_DINF_OPTIMIZER_TIME];
```

```

std::cerr << "(" << douinf[MSK_DINF_SIM_TIME] << ")\n";
std::cerr << "Obj.: " << douinf[MSK_DINF_SIM_OBJ] << std::endl;
break;
case MSK_CALLBACK_END_PRIMAL_SIMPLEX:
std::cerr << "Primal simplex optimizer finished.\n";
break;
case MSK_CALLBACK_BEGIN_DUAL_SIMPLEX:
std::cerr << "Dual simplex optimizer started.\n";
break;
case MSK_CALLBACK_UPDATE_DUAL_SIMPLEX:
std::cerr << "Iterations: " << intinf[MSK_IINF_SIM_DUAL_ITER];
std::cerr << " Elapsed time: " << douinf[MSK_DINF_OPTIMIZER_TIME];
std::cerr << "(" << douinf[MSK_DINF_SIM_TIME] << ")\n";
std::cerr << "Obj.: " << douinf[MSK_DINF_SIM_OBJ] << std::endl;
break;
case MSK_CALLBACK_END_DUAL_SIMPLEX:
std::cerr << "Dual simplex optimizer finished.\n";
break;
case MSK_CALLBACK_BEGIN_BI:
std::cerr << "Basis identification started.\n";
break;
case MSK_CALLBACK_END_BI:
std::cerr << "Basis identification finished.\n";
break;
default:
break;
}
if ( douinf[MSK_DINF_OPTIMIZER_TIME] >= maxtime )
{
std::cerr << "MOSEK is spending too much time.Terminate it.\n";
return 1;
}
return 0;
} /* usercallback */

```

Assuming that we have defined a model *M* and a time limit *maxtime*, the callback function is attached as follows:

Listing 8.5: Attaching the data callback function to the model.

```

auto cllbck = [&](MSKcallbackcodee caller,
                 const double * douinf, const int32_t* intinf, const int64_t* lintinf)
{
return usercallback(caller, douinf, intinf, lintinf, M, maxtime);
};

M->setDataCallbackHandler(cllbck);

```

8.8 Optimizer API Task

This section is intended for advanced users and should normally never be followed unless advanced debugging or very specialized functionalities are required.

The *Model* is a wrapper on top of an underlying **MOSEK** low-level optimizer task. Access to the task is provided by the method *Model.getTask*. The functionalities available from the task are described in the documentation of the relevant Optimizer API.

Warning

Note that the user gets access to the *actual task* in the model, and *not* its clone. Changing the state of the task will most likely invalidate the *Fusion* model.

TECHNICAL GUIDELINES

This section contains some technical guidelines for *Fusion* users.

For modelling guidelines check one of the following sections:

- [Sec. 6](#) for an overview of how to express optimization problems in *Fusion*.
- [Sec. 12](#) for how to address numerical issues in modelling and how to tune the continuous optimizers.
- [Sec. 13](#) for how to tune the mixed-integer optimizer.

9.1 Limitations

Fusion imposes some limitations on certain aspects of a model to ensure easier portability:

- Constraints and variables belong to a single model, and cannot as such be used (e.g. stacked) with objects from other models.
- Most objects forming a *Fusion* model are immutable.

The limits on the model size in *Fusion* are as follows:

- The maximum number of variable elements is $2^{31} - 1$.
- The maximum size of a dimension is $2^{31} - 1$.
- The total size of an item (the product of dimensions) is limited to $2^{63} - 1$.

9.2 Memory management and garbage collection

Users who experience memory leaks using *Fusion*, especially:

- memory usage not decreasing after the solver terminates,
- memory usage increasing when solving a sequence of problems,

should make sure that the *Model* objects are properly garbage collected. Since each *Model* object links to a **MOSEK** task resource in a linked library, it is sometimes the case that the garbage collector is unable to reclaim it automatically. This means that substantial amounts of memory may be leaked. For this reason it is very important to make sure that the *Model* object is disposed of manually when it is not used any more. The necessary cleanup is performed by the method *Model.dispose*.

```
{
    Model::t M = new Model();    auto _M = finally([&]() { M->dispose(); });
    // do something with M
}
```

This construction assures that the *Model.dispose* method is called when the object goes out of scope, even if an exception occurred. If this approach cannot be used, e.g. if the *Model* object is returned by

a factory function, one should explicitly call the `Model.dispose` method when the object is no longer used.

Furthermore, if the `Model` class is extended, it is necessary to dispose of the superclass if the initialization of the derived subclass fails. One can use a construction such as:

```
class MyModel: Model
{
public:
    MyModel(): Model()
    {
        bool finished = false;
        try
        {
            //perform initialization here
            finished = true;
        }
        catch(...)
        {
            dispose();
        }
    }
};
```

9.3 Multithreading

Thread safety

Sharing a `Model` object between threads is safe, as long as it is not accessed from more than one thread at a time. Multiple `Model` objects can be used in parallel without any problems.

Parallelization

The interior-point and mixed-integer optimizers in **MOSEK** are parallelized. By default **MOSEK** will automatically select the number of threads. However, the maximum number of threads allowed can be changed by setting the parameter `numThreads` and related parameters. This should never exceed the number of cores. See [Sec. 12](#) and [Sec. 13](#) for more details for the two optimizer types.

The speed-up obtained when using multiple threads is highly problem and hardware dependent. We recommend experimenting with various thread numbers to determine the optimal settings. For small problems using multiple threads may be counter-productive because of the associated overhead.

By default the optimizer is run-to-run deterministic, which means that it will return the same answer each time it is run on the same machine with the same input, the same parameter settings (including number of threads) and no time limits.

9.4 Efficiency

In some cases *Fusion* must reformulate the problem by adding auxiliary variables and constraints before it can be represented in the optimizer's internal format. This can cause a significant overhead. The following guidelines can help speed up the process.

Decide between sparse and dense matrices

Deciding whether a matrix should be stored in dense or sparse format is not always trivial. First, there are storage considerations. An $n \times m$ matrix with l non zero entries, requires

- $\approx n \cdot m$ storage space in dense format,
- $\approx 3 \cdot l$ storage space in sparse (triplet) format.

Therefore if $l \ll n \cdot m$, then the sparse format has smaller memory requirements. Especially for very sparse density matrices it will also yield much faster expression transformations. Also, this is the format used ultimately by the underlying optimizer task. However, there are borderline cases in which these advantages may vanish due to overhead spent creating the triplet representation.

Sparsity is a key feature of many optimization models and often occurs naturally. For instance, linear constraints arising from networks or multi-period planning are typically sparse. *Fusion* does not detect sparsity but leaves to the user the responsibility of choosing the most appropriate storage format.

Reduce the number of *Fusion* calls and level of nesting

A possible source of performance degradation is an excessive use of nested expressions resulting in a large number of *Fusion* calls with small model updates, where instead the model could be updated in larger chunks at once. In general, loop-free code and reduction of expression nesting are likely to be more efficient. For example the expression

$$\sum_{i=1}^n A_i x_i$$

$$x_i \in \mathbb{R}^k, A_i \in \mathbb{R}^{k \times k},$$

could be implemented in a loop as

```
Expression::t ee = Expr::constTerm(k, 0.0);
for(int i=0; i<n; i++)
    ee = Expr::add( ee, Expr::mul((*A)[i], (*x)[i]) );
```

A better way is to store the intermediate expressions for $A_i x_i$ and sum all of them in one step:

```
auto prods = new ndarray<Expression::t,1>(shape(n));
for(int i=0; i<n; i++) (*prods)[i] = Expr::mul((*A)[i], (*x)[i]);
Expression::t ee = Expr::add( std::shared_ptr<ndarray<Expression::t,1>>(prods) );
```

Fusion design naturally promotes this sort of vectorized implementations. See [Sec. 6.7](#) for more examples.

Do not fetch the whole solution if not necessary

Fetching a solution from a shaped variable produces a flat array of values. This means that some reshaping has to take place and that the user gets all values even if they are potentially interested only in some of them. In this case, it is better to create a slice variable holding the relevant elements and fetch the solution for this subset. See [Sec. 6.6](#). Fetching the full solution may cause an exception due to memory exhaustion or platform-dependent constraints on array sizes.

Remove names

Variables, constraints and the objective function can be constructed with user-assigned names. While this feature is very useful for debugging and improves the readability of both the code and of problems dumped to files, it also introduces quite some overhead: *Fusion* must check and make sure that names are unique. For optimal performance it is therefore recommended to not specify names at all.

9.5 The license system

MOSEK is a commercial product that **always** needs a valid license to work. **MOSEK** uses a third party license manager to implement license checking. The number of license tokens provided determines the number of optimizations that can be run simultaneously.

By default a license token remains checked out from the first optimization until the end of the **MOSEK** session, i.e.

- a license token is checked out when the method `Model.solve` is called the first time, and
- the token is returned when the process exits.

Starting the optimization when no license tokens are available will result in an error.

Default behaviour of the license system can be changed in several ways:

- Setting the parameter `cacheLicense` to `"off"` will force **MOSEK** to return the license token immediately after the optimization completed.
- Setting the license wait flag with `Model.putLicenseWait` or with the parameter `licenseWait` will force **MOSEK** to wait until a license token becomes available instead of throwing an exception.
- Additional license checkouts and checkins can be performed manually through the underlying **MOSEK** task and environment. See [Sec. 8.8](#).
- The default path to the license file can be changed with `Model.putLicensePath`.

9.6 Deployment

When redistributing a C++ application using the **MOSEK** Fusion API for C++ 8.1.0.64, the following libraries must be included:

64-bit Linux	64-bit Windows	64-bit Mac OS
libmosek64.so.8.1	mosek64_8_1.dll	libmosek64.8.1.dylib
libfusion64.so.8.1	fusion64_8_1.lib	libfusion64.8.1.dylib
libiomp5.so	libomp5md.dll	
libcilkrts.so.5	cilkrts20.dll	libcilkrts.5.dylib

CASE STUDIES

In this section we present some case studies in which the Fusion API for C++ is used to solve real-life applications. These examples involve some more advanced modelling skills and possibly some input data. The user is strongly recommended to first read the basic tutorials of [Sec. 7](#) before going through these advanced case studies.

Case Studies	Type	Int.	Keywords
<i>Portfolio Optimization</i>	CQO	NO	stacking, objective function change
<i>Primal SVM</i>	CQO	NO	variable repeat
<i>2D Total Variation</i>	CQO	NO	slicing, sliding windows
<i>Inner and outer Löwner-John Ellipsoids</i>	SDO	NO	determinant root
<i>Nearest Correlation Matrix Problem</i>	SDO	NO	Frobenius norm, nuclear norm
<i>Semidefinite relaxation of MIQCQO problems</i>	SDO	NO	integer least squares
<i>SUDOKU Game</i>	MILP	YES	assignment constraints
<i>Multi Processor Scheduling</i>	MILP	YES	assignment constraints, initial solution
<i>Travelling Salesman</i>	MILP	YES	graph, row generation

10.1 Portfolio Optimization

This case study is devoted to the Portfolio Optimization Problem.

10.1.1 The Basic Model

The classical Markowitz portfolio optimization problem considers investing in n stocks or assets held over a period of time. Let x_j denote the amount invested in asset j , and assume a stochastic model where the return of the assets is a random variable r with known mean

$$\mu = \mathbf{E}r$$

and covariance

$$\Sigma = \mathbf{E}(r - \mu)(r - \mu)^T.$$

The return of the investment is also a random variable $y = r^T x$ with mean (or expected return)

$$\mathbf{E}y = \mu^T x$$

and variance (or risk)

$$\mathbf{E}(y - \mathbf{E}y)^2 = x^T \Sigma x.$$

The problem facing the investor is to rebalance the portfolio to achieve a good compromise between risk and expected return, e.g., maximize the expected return subject to a budget constraint and an upper bound (denoted γ) on the tolerable risk. This leads to the optimization problem

$$\begin{aligned} & \text{maximize} && \mu^T x \\ & \text{subject to} && e^T x = w + e^T x^0, \\ & && x^T \Sigma x \leq \gamma^2, \\ & && x \geq 0. \end{aligned} \tag{10.1}$$

The variables x denotes the investment i.e. x_j is the amount invested in asset j and x_j^0 is the initial holding of asset j . Finally, w is the initial amount of cash available.

A popular choice is $x^0 = 0$ and $w = 1$ because then x_j may be interpreted as the relative amount of the total portfolio that is invested in asset j .

Since e is the vector of all ones then

$$e^T x = \sum_{j=1}^n x_j$$

is the total investment. Clearly, the total amount invested must be equal to the initial wealth, which is

$$w + e^T x^0.$$

This leads to the first constraint

$$e^T x = w + e^T x^0.$$

The second constraint

$$x^T \Sigma x \leq \gamma^2$$

ensures that the variance, or the risk, is bounded by the parameter γ^2 . Therefore, γ specifies an upper bound of the standard deviation the investor is willing to undertake. Finally, the constraint

$$x_j \geq 0$$

excludes the possibility of short-selling. This constraint can of course be excluded if short-selling is allowed.

The covariance matrix Σ is positive semidefinite by definition and therefore there exist a matrix G such that

$$\Sigma = GG^T. \tag{10.2}$$

In general the choice of G is **not** unique and one possible choice of G is the Cholesky factorization of Σ . However, in many cases another choice is better for efficiency reasons as discussed in [Sec. 10.1.2](#). For a given G we have that

$$\begin{aligned} x^T \Sigma x &= x^T G G^T x \\ &= \|G^T x\|^2. \end{aligned}$$

Hence, we may write the risk constraint as

$$\gamma \geq \|G^T x\|$$

or equivalently

$$[\gamma; G^T x] \in \mathcal{Q}^{n+1}.$$

where \mathcal{Q}^{n+1} is the $(n+1)$ -dimensional quadratic cone. Therefore, problem (10.1) can be written as

$$\begin{aligned} & \text{maximize} && \mu^T x \\ & \text{subject to} && e^T x = w + e^T x^0, \\ & && [\gamma; G^T x] \in \mathcal{Q}^{n+1}, \\ & && x \geq 0, \end{aligned} \tag{10.3}$$

which is a conic quadratic optimization problem that can easily be formulated and solved with *Fusion*. Subsequently we will use the example data

$$\mu = \begin{bmatrix} 0.1073 \\ 0.0737 \\ 0.0627 \end{bmatrix}$$

and

$$\Sigma = 0.1 \cdot \begin{bmatrix} 0.2778 & 0.0387 & 0.0021 \\ 0.0387 & 0.1112 & -0.0020 \\ 0.0021 & -0.0020 & 0.0115 \end{bmatrix}.$$

This implies

$$G^T = \sqrt{0.1} \begin{bmatrix} 0.5271 & 0.0734 & 0.0040 \\ 0 & 0.3253 & -0.0070 \\ 0 & 0 & 0.1069 \end{bmatrix}$$

Example code

Listing 10.1 demonstrates how the basic Markowitz model (10.3) is implemented using *Fusion*.

Listing 10.1: Code implementing problem (10.3).

```
double BasicMarkowitz
( int n,
  std::shared_ptr<ndarray<double, 1>> mu,
  std::shared_ptr<ndarray<double, 2>> GT,
  std::shared_ptr<ndarray<double, 1>> x0,
  double w,
  double gamma)
{
  Model::t M = new Model("Basic Markowitz"); auto _M = finally([&]() { M->dispose(); });
  // Redirect log output from the solver to stdout for debugging.
  // M->setLogHandler([](const std::string & msg) { std::cout << msg << std::flush; } );

  // Defines the variables (holdings). Shortselling is not allowed.
  Variable::t x = M->variable("x", n, Domain::greaterThan(0.0));

  // Maximize expected return
  M->objective("obj", ObjectiveSense::Maximize, Expr::dot(mu, x));

  // The amount invested must be identical to initial wealth
  M->constraint("budget", Expr::sum(x), Domain::equalsTo(w + sum(x0)));

  // Imposes a bound on the risk
  M->constraint("risk", Expr::vstack(gamma, Expr::mul(GT, x)), Domain::inQCone());

  // Solves the model.
  M->solve();
}
```

```
return dot(mu, x->level());
}
```

The source code should be self-explanatory except perhaps for

```
M->constraint("risk", Expr::vstack(gamma, Expr::mul(GT, x)), Domain::inQCone());
```

where the linear expression

$$[\gamma; G^T x]$$

is created using the `Expr.vstack` operator. Finally, the linear expression must lie in a quadratic cone implying

$$\gamma \geq \|G^T x\|.$$

10.1.2 The Efficient Frontier

The portfolio computed by the Markowitz model is efficient in the sense that there is no other portfolio giving a strictly higher return for the same amount of risk. An efficient portfolio is also sometimes called a Pareto optimal portfolio. Clearly, an investor should only invest in efficient portfolios and therefore it may be relevant to present the investor with all efficient portfolios so the investor can choose the portfolio that has the desired tradeoff between return and risk.

Given a nonnegative α the problem

$$\begin{aligned} & \text{maximize} && \mu^T x - \alpha s \\ & \text{subject to} && \begin{aligned} e^T x &= w + e^T x^0, \\ [s; G^T x] &\in Q^{n+1}, \\ x &\geq 0. \end{aligned} \end{aligned} \tag{10.4}$$

computes an efficient portfolio. Note that the objective is to maximize the expected return while minimizing the standard deviation. The parameter α specifies the tradeoff between expected return and risk. Ideally the problem (10.4) should be solved for all values $\alpha \geq 0$ but in practice it is impossible. Using the example data from [Sec. 10.1.1](#), the optimal values of return and risk for several α s are listed below:

Efficient frontier

alpha	return	risk
0.0000	1.0730e-01	7.2700e-01
0.0100	1.0730e-01	1.6667e-01
0.1000	1.0730e-01	1.6667e-01
0.2500	1.0321e-01	1.4974e-01
0.3000	8.0529e-02	6.8144e-02
0.3500	7.4290e-02	4.8585e-02
0.4000	7.1958e-02	4.2309e-02
0.4500	7.0638e-02	3.9185e-02
0.5000	6.9759e-02	3.7327e-02

Example code

[Listing 10.2](#) demonstrates how to compute the efficient portfolios for several values of α in *Fusion*.

Listing 10.2: Code for the computation of the efficient frontier based on problem (10.4).

```

void EfficientFrontier
( int n,
  std::shared_ptr<ndarray<double, 1>> mu,
  std::shared_ptr<ndarray<double, 2>> GT,
  std::shared_ptr<ndarray<double, 1>> x0,
  double w,
  std::vector<double> & alphas,
  std::vector<double> & frontier_mux,
  std::vector<double> & frontier_s)
{
    Model::t M = new Model("Efficient frontier"); auto M_ = finally([&]() { M->dispose(); });

    // Defines the variables (holdings). Shortselling is not allowed.
    Variable::t x = M->variable("x", n, Domain::greaterThan(0.0)); // Portfolio variables
    Variable::t s = M->variable("s", 1, Domain::unbounded()); // Risk variable

    M->constraint("budget", Expr::sum(x), Domain::equalsTo(w + sum(x0)));

    // Computes the risk
    M->constraint("risk", Expr::vstack(s, Expr::mul(GT, x)), Domain::inQCone());

    Expression::t mudotx = Expr::dot(mu, x);

    for (double alpha : alphas)
    {
        // Define objective as a weighted combination of return and risk
        M->objective("obj", ObjectiveSense::Maximize, Expr::sub(mudotx, Expr::mul(alpha, s)));

        M->solve();

        frontier_mux.push_back(dot(mu, x->level()));
        frontier_s.push_back((*s->level())[0]);
    }
}

```

Note the efficient frontier could also have been computed using the code in [Sec. 10.1.1](#) by varying γ . However, when the constraints of a *Fusion* model are changed the model has to be rebuilt whereas a rebuild is not needed if only the objective is modified.

10.1.3 Improving the Computational Efficiency

In practice it is often important to solve the portfolio problem very quickly. Therefore, in this section we discuss how to improve computational efficiency at the modelling stage.

The computational cost is of course to some extent dependent on the number of constraints and variables in the optimization problem. However, in practice a more important factor is the sparsity: the number of nonzeros used to represent the problem. Indeed it is often better to focus on the number of nonzeros in G see (10.2) and try to reduce that number by for instance changing the choice of G .

In other words if the computational efficiency should be improved then it is always good idea to start with focusing at the covariance matrix. As an example assume that

$$\Sigma = D + VV^T$$

where D is a positive definite diagonal matrix. Moreover, V is a matrix with n rows and p columns. Such a model for the covariance matrix is called a factor model and usually p is much smaller than n . In practice p tends to be a small number independent of n , say less than 100.

One possible choice for G is the Cholesky factorization of Σ which requires storage proportional to $n(n+1)/2$. However, another choice is

$$G^T = \begin{bmatrix} D^{1/2} \\ V^T \end{bmatrix}$$

because then

$$GG^T = D + VV^T.$$

This choice requires storage proportional to $n + pn$ which is much less than for the Cholesky choice of G . Indeed assuming p is a constant storage requirements are reduced by a factor of n .

The example above exploits the so-called factor structure and demonstrates that an alternative choice of G may lead to a significant reduction in the amount of storage used to represent the problem. This will in most cases also lead to a significant reduction in the solution time.

The lesson to be learned is that it is important to investigate how the covariance matrix is formed. Given this knowledge it might be possible to make a special choice for G that helps reducing the storage requirements and enhance the computational efficiency. More details about this process can be found in [\[And13\]](#).

10.1.4 Slippage Cost

The basic Markowitz model assumes that there are no costs associated with trading the assets and that the returns of the assets are independent of the amount traded. Neither of those assumptions is usually valid in practice. Therefore, a more realistic model is

$$\begin{aligned} & \text{maximize} && \mu^T x \\ & \text{subject to} && e^T x + \sum_{j=1}^n T_j(x_j - x_j^0) = w + e^T x^0, \\ & && x^T \Sigma x \leq \gamma^2, \\ & && x \geq 0, \end{aligned} \tag{10.5}$$

where the function

$$T_j(x_j - x_j^0)$$

specifies the transaction costs when the holding of asset j is changed from its initial value.

10.1.5 Market Impact Costs

If the initial wealth is fairly small and no short selling is allowed, then the holdings will be small and the traded amount of each asset must also be small. Therefore, it is reasonable to assume that the prices of the assets are independent of the amount traded. However, if a large volume of an asset is sold or purchased, the price, and hence return, can be expected to change. This effect is called market impact costs. It is common to assume that the market impact cost for asset j can be modelled by

$$T_j = m_j \sqrt{|x_j - x_j^0|}$$

where m_j is a constant that is estimated in some way by the trader. See [\[GK00\]](#) [p. 452] for details. Hence, we have

$$T_j(x_j - x_j^0) = m_j |x_j - x_j^0| \sqrt{|x_j - x_j^0|} = m_j |x_j - x_j^0|^{3/2}.$$

From [\[MOSEKApS12\]](#) it is known that

$$\{(t, z) : t \geq z^{3/2}, z \geq 0\} = \{(t, z) : (v, t, z), (z, 1/8, v) \in \mathcal{Q}_r^3\}$$

where \mathcal{Q}_r^3 is the 3-dimensional rotated quadratic cone. Hence, it follows

$$\begin{aligned} z_j &= |x_j - x_j^0|, \\ (v_j, t_j, z_j), (z_j, 1/8, v_j) &\in \mathcal{Q}_r^3, \\ \sum_{j=1}^n T_j(x_j - x_j^0) &= \sum_{j=1}^n t_j. \end{aligned}$$

Unfortunately this set of constraints is nonconvex due to the constraint

$$z_j = |x_j - x_j^0| \quad (10.6)$$

but in many cases the constraint may be replaced by the relaxed constraint

$$z_j \geq |x_j - x_j^0|, \quad (10.7)$$

which is equivalent to

$$\begin{aligned} z_j &\geq x_j - x_j^0, \\ z_j &\geq -(x_j - x_j^0). \end{aligned} \quad (10.8)$$

For instance if the universe of assets contains a risk free asset then

$$z_j > |x_j - x_j^0| \quad (10.9)$$

cannot hold for an optimal solution.

If the optimal solution has the property (10.9) then the market impact cost within the model is larger than the true market impact cost and hence money are essentially considered garbage and removed by generating transaction costs. This may happen if a portfolio with very small risk is requested because the only way to obtain a small risk is to get rid of some of the assets by generating transaction costs. We generally assume that this is not the case and hence the models (10.6) and (10.7) are equivalent.

The above observations lead to

$$\begin{aligned} &\text{maximize} && \mu^T x \\ &\text{subject to} && e^T x + m^T t = w + e^T x^0, \\ & && [\gamma; G^T x] \in \mathcal{Q}^{n+1}, \\ & && z_j \geq x_j - x_j^0, \quad j = 1, \dots, n, \\ & && z_j \geq x_j^0 - x_j, \quad j = 1, \dots, n, \\ & && [v_j; t_j; z_j], [z_j; 1/8; v_j] \in \mathcal{Q}_r^3, \quad j = 1, \dots, n, \\ & && x \geq 0. \end{aligned} \quad (10.10)$$

The revised budget constraint

$$e^T x + m^T t = w + e^T x^0$$

specifies that the initial wealth covers the investment and the transaction costs. Moreover, v and z are auxiliary variables that model the market impact cost so that $z_j \geq |x_j - x_j^0|$ and $t_j \geq z_j^{3/2}$.

It should be mentioned that transaction costs of the form

$$c_j \geq z_j^{p/q}$$

where p and q are both integers and $p \geq q$ can be modelled using quadratic cones. See [\[MOSEKApS12\]](#) for details.

Example code

[Listing 10.3](#) demonstrates how to compute an optimal portfolio when market impact cost are included using *Fusion*.

Listing 10.3: Implementation of model (10.10).

```

void MarkowitzWithMarketImpact
(
  int n,
  std::shared_ptr<ndarray<double, 1>> mu,
  std::shared_ptr<ndarray<double, 2>> GT,
  std::shared_ptr<ndarray<double, 1>> x0,
  double w,
  double gamma,
  std::shared_ptr<ndarray<double, 1>> m,
  std::vector<double> & xsol,
  std::vector<double> & tsol)
{
  Model::t M = new Model("Markowitz portfolio with market impact"); auto M_ = finally([&]() {
    M->dispose(); });

  // Defines the variables. No shortselling is allowed.
  Variable::t x = M->variable("x", n, Domain::greaterThan(0.0));

  // Additional "helper" variables
  Variable::t t = M->variable("t", n, Domain::unbounded());
  Variable::t z = M->variable("z", n, Domain::unbounded());
  Variable::t v = M->variable("v", n, Domain::unbounded());

  // Maximize expected return
  M->objective("obj", ObjectiveSense::Maximize, Expr::dot(mu, x));

  // Invested amount + slippage cost = initial wealth
  M->constraint("budget", Expr::add(Expr::sum(x), Expr::dot(m, t)), Domain::equalsTo(w +
    sum(x)));

  // Imposes a bound on the risk
  M->constraint("risk", Expr::vstack( gamma, Expr::mul(GT, x)),
    Domain::inQCone());

  // z >= |x-x0|
  M->constraint("buy", Expr::sub(z, Expr::sub(x, x0)), Domain::greaterThan(0.0));
  M->constraint("sell", Expr::sub(z, Expr::sub(x0, x)), Domain::greaterThan(0.0));

  // t >= z^1.5, z >= 0.0. Needs two rotated quadratic cones to model this term
  M->constraint("ta", Expr::hstack(v, t, z), Domain::inRotatedQCone());
  M->constraint("tb", Expr::hstack(z, Expr::constTerm(n, 1.0 / 8.0), v),
    Domain::inRotatedQCone());

  M->solve();

  xsol.resize(n);
  tsol.resize(n);
  auto xlvl = x->level();
  auto tlvl = t->level();

  std::copy(xlvl->flat_begin(), xlvl->flat_end(), xsol.begin());
  std::copy(tlvl->flat_begin(), tlvl->flat_end(), tsol.begin());
}

```

The major new features compared to the previous examples are

```
M->constraint("ta", Expr::hstack(v, t, z), Domain::inRotatedQCone());
```

and

```
M->constraint("tb", Expr::hstack(z, Expr::constTerm(n, 1.0 / 8.0), v),
             Domain::inRotatedQCone());
```

In the first line the variables v , t and z are stacked horizontally which corresponds to creating a list of linear expressions where the j 'th element has the form

$$\begin{bmatrix} v_j \\ t_j \\ z_j \end{bmatrix}$$

and finally each linear expression is constrained to a rotated quadratic cone i.e.

$$2v_j t_j \geq z_j^2 \text{ and } v_j, t_j \geq 0.$$

Similarly the second line is equivalent to the constraint

$$\begin{bmatrix} z_j \\ 1/8 \\ v_j \end{bmatrix} \in \mathcal{Q}_r^3$$

or equivalently

$$2z_j \frac{1}{8} \geq v_j^2 \text{ and } z_j \geq 0.$$

10.1.6 Transaction Costs

Now assume there is a cost associated with trading asset j given by

$$T_j(\Delta x_j) = \begin{cases} 0, & \Delta x_j = 0, \\ f_j + g_j |\Delta x_j|, & \text{otherwise.} \end{cases}$$

Here Δx_j is the change in the holding of asset j i.e.

$$\Delta x_j = x_j - x_j^0.$$

Hence, whenever asset j is traded we pay a fixed setup cost f_j and a variable cost of g_j per unit traded. Given the assumptions about transaction costs in this section problem (10.5) may be formulated as

$$\begin{aligned} & \text{maximize} && \mu^T x \\ & \text{subject to} && e^T x + \sum_{j=1}^n (f_j y_j + g_j z_j) = w + e^T x^0, \\ & && [\gamma; G^T x] \in \mathcal{Q}^{n+1}, \\ & && z_j \geq x_j - x_j^0, & j = 1, \dots, n, \\ & && z_j \geq x_j^0 - x_j, & j = 1, \dots, n, \\ & && z_j \leq U_j y_j, & j = 1, \dots, n, \\ & && y_j \in \{0, 1\}, & j = 1, \dots, n, \\ & && x \geq 0. \end{aligned} \tag{10.11}$$

First observe that

$$z_j \geq |x_j - x_j^0| = |\Delta x_j|.$$

Here U_j is some a priori chosen upper bound on the amount of trading in asset j and therefore if $z_j > 0$ then $y_j = 1$ has to be the case. This implies that the transaction costs for the asset j is given by

$$f_j y_j + g_j z_j.$$

Example code

The following example code demonstrates how to compute an optimal portfolio when transaction costs are included.

Listing 10.4: Code solving problem (10.11).

```
std::shared_ptr<ndarray<double, 1>> MarkowitzWithTransactionsCost
( int n,
  std::shared_ptr<ndarray<double, 1>> mu,
  std::shared_ptr<ndarray<double, 2>> GT,
  std::shared_ptr<ndarray<double, 1>> x0,
  double w,
  double gamma,
  std::shared_ptr<ndarray<double, 1>> f,
  std::shared_ptr<ndarray<double, 1>> g)
{
  // Upper bound on the traded amount
  std::shared_ptr<ndarray<double, 1>> u(new ndarray<double, 1>(shape_t<1>(n), w + sum(x0)));

  Model::t M = new Model("Markowitz portfolio with transaction costs"); auto M_ = finally([&
  ↪]() { M->dispose(); });

  // Defines the variables. No shortselling is allowed.
  Variable::t x = M->variable("x", n, Domain::greaterThan(0.0));

  // Additional "helper" variables
  Variable::t z = M->variable("z", n, Domain::unbounded());
  // Binary variables
  Variable::t y = M->variable("y", n, Domain::binary());

  // Maximize expected return
  M->objective("obj", ObjectiveSense::Maximize, Expr::dot(mu, x));

  // Invest amount + transactions costs = initial wealth
  M->constraint("budget", Expr::add(Expr::add(Expr::sum(x), Expr::dot(f, y)), Expr::dot(g, z)),
    Domain::equalsTo(w + sum(x0)));

  // Imposes a bound on the risk
  M->constraint("risk", Expr::vstack( gamma, Expr::mul(GT, x)),
    Domain::inQCone());

  // z >= |x-x0|
  M->constraint("buy", Expr::sub(z, Expr::sub(x, x0)), Domain::greaterThan(0.0));
  M->constraint("sell", Expr::sub(z, Expr::sub(x0, x)), Domain::greaterThan(0.0));
  // Alternatively, formulate the two constraints as
  //M->constraint("trade", Expr::hstack(z, Expr::sub(x, x0)), Domain::inQCone());

  // Constraints for turning y off and on. z-diag(u)*y<=0 i.e. z_j <= u_j*y_j
  M->constraint("y_on_off", Expr::sub(z, Expr::mul(Matrix::diag(u), y)), Domain::lessThan(0.
  ↪0));

  // Integer optimization problems can be very hard to solve so limiting the
  // maximum amount of time is a valuable safe guard
  M->setSolverParam("mioMaxTime", 180.0);
  M->solve();

  return x->level();
}
```

10.2 Primal Support-Vector Machine (SVM)

Machine-Learning (ML) has become a common widespread tool in many applications that affect our everyday life. In many cases, at the very core of these techniques there is an optimization problem. This case study focuses on the Support-Vector Machines (SVM).

The basic SVM model can be stated as:

We are given a set of m points in \mathbb{R}^n , partitioned into two groups. Find, if any, the separating hyperplane of the two subsets with the largest margin, i.e. as far as possible from the points.

Mathematical Model

Let $x_1, \dots, x_m \in \mathbb{R}^n$ be the given training set and let $y_i \in \{-1, +1\}$ be the labels indicating the group membership of the i -th training example. Then we want to determine an affine hyperplane $w^T x = b$ that separates the group in the strong sense that

$$y_i(w^T x_i - b) \geq 1 \quad (10.12)$$

for all i , the property referred to as *large margin classification*: the strip $\{x \in \mathbb{R}^n : -1 < w^T x - b < 1\}$ does not contain any training example. The width of this strip is $2\|w\|^{-1}$, and maximizing that quantity is equivalent to minimizing $\|w\|$. We get that the large margin classification is the solution of the following optimization problem:

$$\begin{aligned} & \text{minimize}_{b,w} \quad \frac{1}{2}\|w\|^2 \\ & \text{subject to} \quad y_i(w^T x_i - b) \geq 1 \quad i = 1, \dots, m. \end{aligned}$$

If a solution exists, w, b define the separating hyperplane and the sign of $w^T x - b$ can be used to decide the class in which a point x falls.

To allow more flexibility the soft-margin SVM classifier is often used instead. It admits a violation of the large margin requirement (10.12) by a non-negative slack variable which is then penalized in the objective function.

$$\begin{aligned} & \text{minimize}_{b,w} \quad \frac{1}{2}\|w\|^2 + C \sum_{i=1}^m \xi_i \\ & \text{subject to} \quad y_i(w^T x_i - b) \geq 1 - \xi_i \quad i = 1, \dots, m, \\ & \quad \quad \quad \xi_i \geq 0 \quad i = 1, \dots, m. \end{aligned}$$

In matrix form we have

$$\begin{aligned} & \text{minimize}_{b,w,\xi} \quad \frac{1}{2}\|w\|^2 + C\mathbf{e}^T \xi \\ & \text{subject to} \quad y \star (Xw - b\mathbf{e}) + \xi \geq \mathbf{e}, \\ & \quad \quad \quad \xi \geq 0. \end{aligned}$$

where \star denotes the component-wise product, and \mathbf{e} a vector with all components equal to one. The constant $C \geq 0$ acts both as scaling factor and as weight. Varying C yields different trade-offs between accuracy and robustness.

Implementing the matrix formulation of the soft-margin SVM in *Fusion* is very easy. We only need to cast the problem in conic form, which in this case involves converting the quadratic term of the objective function into a conic constraint:

$$\begin{aligned} & \text{minimize}_{b,w,\xi,t} \quad t + C\mathbf{e}^T \xi \\ & \text{subject to} \quad \xi + y \star (Xw - b\mathbf{e}) \geq \mathbf{e}, \\ & \quad \quad \quad (1, t, w) \in \mathcal{Q}_r^{n+2}, \\ & \quad \quad \quad \xi \geq 0. \end{aligned} \quad (10.13)$$

where \mathcal{Q}_r^{n+2} denotes a rotated cone of dimension $n+2$.

Fusion implementation

We now demonstrate how implement model (10.13). Let us assume that the training examples are stored in the rows of a matrix X , the labels in a vector y and that we have a set of weights C for which we want to train the model. The implementation in *Fusion* of our conic model starts declaring the model class:

```
Model::t M = new Model("primal SVM"); auto _M = finally([&]() { M->dispose(); });
```

Then we proceed defining the variables :

```
Variable::t w = M->variable( n, Domain::unbounded());
Variable::t t = M->variable( 1, Domain::unbounded());
Variable::t b = M->variable( 1, Domain::unbounded());
Variable::t xi = M->variable( m, Domain::greaterThan(0.));
```

The conic constraint is obtained by stacking the three values:

```
M->constraint( Expr::vstack(1., t, w) , Domain::inRotatedQCone() );
```

Note how the dimension of the cone is deduced from the arguments. The relaxed classification constraints can be expressed using the built-in expressions available in *Fusion*. In particular:

1. element-wise multiplication \star is performed with the *Expr.mulElm* function;
2. a vector whose entries are repetitions of b is produced by *Var.repeat*.

The results is

```
auto ex = Expr::sub( Expr::mul(X, w), Var::repeat(b, m) );
M->constraint( Expr::add(Expr::mulElm( y, ex ), xi ) , Domain::greaterThan( 1. ) );
```

Finally, the objective function is defined as

```
M->objective( ObjectiveSense::Minimize, Expr::add( t, Expr::mul(c, Expr::sum(xi) ) ) );
```

To solve a sequence of problems with varying C we can simply iterate along those values changing the objective function:

```
std::cout << "   c   | b       | w\n";
for (int i = 0; i < nc; i++)
{
    double c = 500.0 * i;
    M->objective( ObjectiveSense::Minimize, Expr::add( t, Expr::mul(c, Expr::sum(xi) ) ) );
    M->solve();

    try
    {
        std::cout << std::setw(6) << c << " | " << std::setw(8) << (*(b->level())) [0] << " | ";
        std::cout.width(8);
        auto wlev = w->level();
        std::copy( wlev->begin(), wlev->end() , std::ostream_iterator<double>(std::cout, " ") );
        std::cout << "\n";
    }
    catch (...) {}
}
```

Source code

Listing 10.5: The code implementing model (10.13)

```

Model::t M = new Model("primal SVM"); auto _M = finally([&]() { M->dispose(); });

Variable::t w = M->variable( n, Domain::unbounded());
Variable::t t = M->variable( 1, Domain::unbounded());
Variable::t b = M->variable( 1, Domain::unbounded());
Variable::t xi = M->variable( m, Domain::greaterThan(0.));

auto ex = Expr::sub( Expr::mul(X, w), Var::repeat(b, m) );
M->constraint( Expr::add(Expr::mulElm( y, ex ), xi ), Domain::greaterThan( 1. ) );

M->constraint( Expr::vstack(1., t, w) , Domain::inRotatedQCone() );
M->acceptedSolutionStatus(AccSolutionStatus::NearOptimal);

std::cout << "   c   | b       | w\n";
for (int i = 0; i < nc; i++)
{
    double c = 500.0 * i;
    M->objective( ObjectiveSense::Minimize, Expr::add( t, Expr::mul(c, Expr::sum(xi) ) ) );
    M->solve();

    try
    {
        std::cout << std::setw(6) << c << " | " << std::setw(8) << (*(b->level())) [0] << " | ";
        std::cout.width(8);
        auto wlev = w->level();
        std::copy( wlev->begin(), wlev->end() , std::ostream_iterator<double>(std::cout, " ") );
        std::cout << "\n";
    }
    catch (...) {}
}
}

```

Example

We generate a random dataset consisting of two groups of points, each from a Gaussian distribution in \mathbb{R}^2 with centres (1.0, 1.0) and (-1.0, -1.0), respectively.

```

int m = 50 ;
int n = 3;
int nc = 10;

int nump = m / 2;
int numm = m - nump;

auto y = new_array_ptr<double, 1> (m);
std::fill( y->begin(), y->begin() + nump, 1.);
std::fill( y->begin() + nump, y->end(), -1.);

double mean = 1.;
double var = 1.;

auto X = std::shared_ptr< ndarray<double, 2> > ( new ndarray<double, 2> ( shape_t<2>(m, n)
↪ ) );

std::mt19937 e2(0);

for (int i = 0; i < nump; i++)

```

```

{
    auto ram = std::bind(std::normal_distribution<>(mean, var), e2);
    for ( int j = 0; j < n; j++)
        (*X)(i, j) = ram();
}

std::cout << "Number of data      : " << m << std::endl;
std::cout << "Number of features: " << n << std::endl;

```

With standard deviation $\sigma = 1/2$ we obtain a separable instance of the problem with a solution shown in Fig. 10.1.

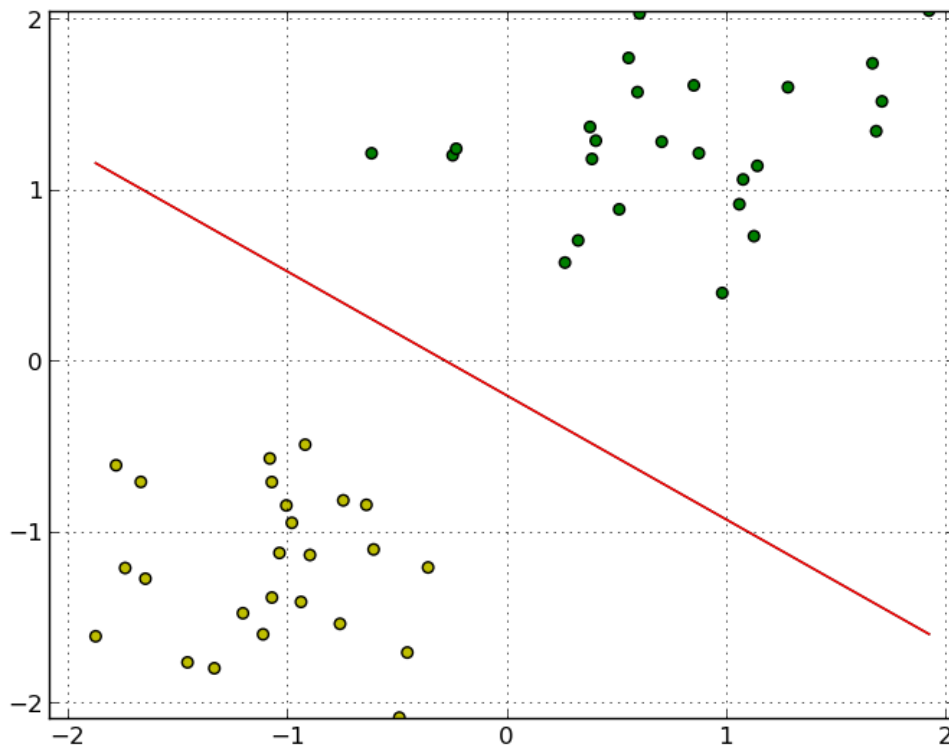

Fig. 10.1: Separating hyperplane for two clusters of points.

For $\sigma = 1$ the two groups are not linearly separable and we obtain the optimal hyperplane as in Fig. 10.2.

10.3 2D Total Variation

This case study is based mainly on the paper by Goldfarb and Yin [GY05].

Mathematical Formulation

We are given a $n \times m$ grid and for each cell (i, j) an observed value f_{ij} that can be expressed as

$$f_{ij} = u_{ij} + v_{ij},$$

Fig. 10.2: Soft separating hyperplane for two groups of points.

where $u_{ij} \in [0, 1]$ is the actual signal value and v_{ij} is the noise. The aim is to reconstruct u subtracting the noise from the observations.

We assume the 2-norm of the overall noise to be bounded: the corresponding constraint is

$$\|u - f\|_2 \leq \sigma$$

which translates into a simple conic quadratic constraint as

$$(\sigma, u - f) \in \mathcal{Q}.$$

We aim to minimize the change in signal value when moving between adjacent cells. To this end we define the adjacent differences vector as

$$\partial_{ij}^+ = \begin{pmatrix} \partial_{ij}^x \\ \partial_{ij}^y \end{pmatrix} = \begin{pmatrix} u_{i+1,j} - u_{i,j} \\ u_{i,j+1} - u_{i,j} \end{pmatrix}, \quad (10.14)$$

for each cell $1 \leq i, j \leq n$ (we assume that the respective coordinates ∂_{ij}^x and ∂_{ij}^y are zero on the right and bottom boundary of the grid).

For each cell we want to minimize the norm of ∂_{ij}^+ , and therefore we introduce auxiliary variables t_{ij} such that

$$t_{ij} \geq \|\partial_{ij}^+\|_2 \quad \text{or} \quad (t_{ij}, \partial_{ij}^+) \in \mathcal{Q},$$

and minimize the sum of all t_{ij} .

The complete model takes the form:

$$\begin{aligned} \min \quad & \sum_{1 \leq i, j \leq n} t_{ij}, \\ \text{s.t.} \quad & \partial_{ij}^+ = (u_{i+1,j} - u_{i,j}, u_{i,j+1} - u_{i,j})^T, \quad \forall 1 \leq i, j \leq n, \\ & (t_{ij}, \partial_{ij}^+) \in \mathcal{Q}^3, \quad \forall 1 \leq i, j \leq n, \\ & (\sigma, u - f) \in \mathcal{Q}^{nm+1}, \\ & u_{i,j} \in [0, 1], \quad \forall 1 \leq i, j \leq n. \end{aligned} \quad (10.15)$$

Implementation

The *Fusion* implementation of model (10.15) uses variable and expression slices.

First of all we start by creating the optimization model and variables \mathbf{t} and \mathbf{u} :

```
Model::t M = new Model("TV"); auto _M = finally([&]() { M->dispose(); });

auto u = M->variable(new_array_ptr<int, 1>({nrows + 1, ncols + 1}), Domain::inRange(0., 1.
↪));
auto t = M->variable(new_array_ptr<int, 1>({nrows, ncols}), Domain::unbounded());
```

Note the dimensions of \mathbf{u} is larger than those of the grid to accommodate the boundary conditions later. The actual cells of the grid are defined as a slice of \mathbf{u} :

```
auto ucore = u->slice(new_array_ptr<int, 1>({0, 0}), new_array_ptr<int, 1>({nrows, ncols}));
```

The next step is to define the partial variation along each axis, as in (10.14):

```
auto deltax = Expr::sub( u->slice( new_array_ptr<int, 1>({1, 0}), new_array_ptr<int, 1>({
↪nrows + 1, ncols}) ), ucore);
auto deltay = Expr::sub( u->slice( new_array_ptr<int, 1>({0, 1}), new_array_ptr<int, 1>({
↪nrows, ncols + 1}) ), ucore);
```

Slices are created on the fly as they will not be reused. Now we can set the conic constraints on the norm of the total variations. To this extent we stack the variables `t`, `deltax` and `deltay` together and demand that each row of the new matrix is in a quadratic cone.

```
M->constraint( Expr::stack(2., t, deltax, deltax), Domain::inQCone()->axis(2) );
```

We now need to bound the norm of the noise. This can be achieved with a conic constraint using `f` as a one-dimensional array:

```
M->constraint( Expr::vstack(sigma, Expr::flatten( Expr::sub( Matrix::dense(nrows, ncols, f),  
↪ ucore ) ) ), Domain::inQCone() );
```

The objective function is the sum of all t_{ij} :

```
M->objective( ObjectiveSense::Minimize, Expr::sum(t) );
```

Example

Consider the linear signal $u_{ij} = \frac{i+j}{n+m}$ and its modification with random Gaussian noise, as in Fig. 10.3. Various reconstructions of u , obtained with different values of σ , are shown in Fig. 10.4 (where $\bar{\sigma} = \sigma/nm$ is the relative noise bound per cell).

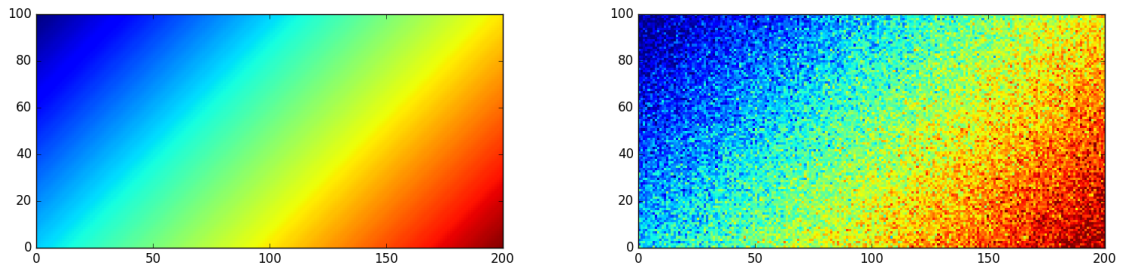

Fig. 10.3: A linear signal and its modification with random Gaussian noise.

Fig. 10.4: Three reconstructions of the linear signal obtained for $\bar{\sigma} \in \{0.0004, 0.0005, 0.0006\}$, respectively.

Source code

Listing 10.6: The *Fusion* implementation of model (10.15).

```

Model::t M = new Model("TV"); auto _M = finally([&]() { M->dispose(); });

auto u = M->variable(new_array_ptr<int, 1>({nrows + 1, ncols + 1}), Domain::inRange(0., 1.
↪));
auto t = M->variable(new_array_ptr<int, 1>({nrows, ncols}), Domain::unbounded());
auto ucore = u->slice(new_array_ptr<int, 1>({0, 0}), new_array_ptr<int, 1>({nrows, ncols}));

auto deltax = Expr::sub( u->slice( new_array_ptr<int, 1>({1, 0}), new_array_ptr<int, 1>({
↪nrows + 1, ncols}) ), ucore);
auto deltax = Expr::sub( u->slice( new_array_ptr<int, 1>({0, 1}) , new_array_ptr<int, 1>({
↪nrows, ncols + 1}) ), ucore);

M->constraint( Expr::stack(2., t, deltax, deltax), Domain::inQCone()->axis(2) );

M->constraint( Expr::vstack(sigma, Expr::flatten( Expr::sub( Matrix::dense(nrows, ncols, f), u
↪ ucore ) ) ), Domain::inQCone() );

M->objective( ObjectiveSense::Minimize, Expr::sum(t) );
M->setLogHandler([](const std::string & msg) { std::cout << msg << std::flush; } );
M->solve();

std::vector<double> deltas(ncells);
auto uu = *(u->level());
for (int i = 0; i < ncells; i++)
    deltas[i] = std::abs( uu[i] - (*f)[i] );

```

10.4 Inner and outer Löwner-John Ellipsoids

In this section we show how to compute the Löwner-John *inner* and *outer* ellipsoidal approximations of a polytope. They are defined as, respectively, the largest volume ellipsoid contained inside the polytope and the smallest volume ellipsoid containing the polytope, as seen in Fig. 10.5.

Fig. 10.5: The inner and outer Löwner-John ellipse of a polygon.

For further mathematical details, such as uniqueness of the two ellipsoids, consult [BenTalN01]. Our solution is a mix of conic quadratic and semidefinite programming. Among other things, in Sec. 10.4.3 we show how to implement bounds involving the determinant of a PSD matrix.

10.4.1 Inner Löwner-John Ellipsoids

Suppose we have a polytope given by an h-representation

$$\mathcal{P} = \{x \in \mathbb{R}^n \mid Ax \leq b\}$$

and we wish to find the inscribed ellipsoid with maximal volume. It will be convenient to parametrize the ellipsoid as an affine transformation of the standard disk:

$$\mathcal{E} = \{x \mid x = Cu + d, u \in \mathbb{R}^n, \|u\|_2 \leq 1\}.$$

Every non-degenerate ellipsoid has a parametrization such that C is a positive definite symmetric $n \times n$ matrix. Now the volume of \mathcal{E} is proportional to $\det(C)^{1/n}$. The condition $\mathcal{E} \subseteq \mathcal{P}$ is equivalent to the inequality $A(Cu + d) \leq b$ for all u with $\|u\|_2 \leq 1$. After a short computation we obtain the formulation:

$$\begin{aligned} & \text{maximize} && t \\ & \text{subject to} && t \leq \det(C)^{1/n}, \\ & && (b - Ad)_i \geq \|(AC)_i\|_2, \quad i = 1, \dots, m, \\ & && C \succeq 0, \end{aligned} \tag{10.16}$$

where X_i denotes the i -th row of the matrix X . This can easily be implemented using *Fusion*, where the sequence of conic inequalities can be realized at once by feeding in the matrices $b - Ad$ and AC .

Listing 10.7: *Fusion* implementation of model (10.16).

```
std::pair<std::shared_ptr<ndarray<double, 1>>, std::shared_ptr<ndarray<double, 1>>>
  lowerjohn_inner
  ( std::shared_ptr<ndarray<double, 2>> A,
    std::shared_ptr<ndarray<double, 1>> b)
{
  Model::t M = new Model("lowerjohn_inner"); auto _M = finally([&]() { M->dispose(); });
  int m = A->size(0);
  int n = A->size(1);

  // Setup variables
  Variable::t t = M->variable("t", 1, Domain::greaterThan(0.0));
  Variable::t C = M->variable("C", Domain::inPSDCone(n));
  Variable::t d = M->variable("d", n, Domain::unbounded());

  // quadratic cones
  M->constraint(Expr::hstack(Expr::sub(b, Expr::mul(A, d)), Expr::mul(A, C)),
               Domain::inQCone());

  // t <= det(C)^{1/n}
  //model_utils.det_rootn(M, C, t);
  det_rootn(M, n, C, t);

  // Objective: Maximize t
  M->objective(ObjectiveSense::Maximize, t);
  M->solve();

  return std::make_pair(C->level(), d->level());
}
```

The only black box is the method `det_rootn` which implements the constraint $t \leq \det(C)^{1/n}$. It will be described in [Sec. 10.4.3](#).

10.4.2 Outer Löwner-John Ellipsoids

To compute the outer ellipsoidal approximation to a polytope, let us now start with a v-representation

$$\mathcal{P} = \text{conv}\{x_1, x_2, \dots, x_m\} \subseteq \mathbb{R}^n,$$

of the polytope as a convex hull of a set of points. We are looking for an ellipsoid given by a quadratic inequality

$$\mathcal{E} = \{x \in \mathbb{R}^n \mid \|Px - c\|_2 \leq 1\},$$

whose volume is proportional to $\det(P)^{-1/n}$, so we are after maximizing $\det(P)^{1/n}$. Again, there is always such a representation with a symmetric, positive definite matrix P . The inclusion conditions $x_i \in \mathcal{E}$ translate into a straightforward problem formulation:

$$\begin{aligned} & \text{maximize} && t \\ & \text{subject to} && t \leq \det(P)^{1/n}, \\ & && \|Px_i - c\|_2 \leq 1, \quad i = 1, \dots, m, \\ & && P \succeq 0, \end{aligned} \tag{10.17}$$

and then directly into *Fusion* code:

Listing 10.8: *Fusion* implementation of model (10.17).

```
std::pair<std::shared_ptr<ndarray<double, 1>>, std::shared_ptr<ndarray<double, 1>>>
  lowerjohn_outer(std::shared_ptr<ndarray<double, 2>> x)
{
  Model::t M = new Model("lowerjohn_outer");
  int m = x->size(0);
  int n = x->size(1);

  // Setup variables
  Variable::t t = M->variable("t", 1, Domain::greaterThan(0.0));
  Variable::t P = M->variable("P", Domain::inPSDCone(n));
  Variable::t c = M->variable("c", n, Domain::unbounded());

  // (1, Px-c) \in Q
  M->constraint(Expr::hstack(
    Expr::ones(m), Expr::sub(Expr::mul(x, P),
      Var::reshape(Var::repeat(c, m), new_array_ptr<int, 1>({m, n}))),
    Domain::inQCone());

  // t <= det(P)^{1/n}
  //model_utils.det_rootn(M, P, t);
  det_rootn(M, n, P, t);

  // Objective: Maximize t
  M->objective(ObjectiveSense::Maximize, t);
  M->solve();

  return std::make_pair(P->level(), c->level());
}
```

10.4.3 Bound on the Determinant Root

It remains to show how to express the bounds on $\det(X)^{1/n}$ for a symmetric positive definite $n \times n$ matrix X using PSD and conic quadratic variables. We want to model the set

$$C = \{(X, t) \in \mathcal{S}_+^n \times \mathbb{R} \mid t \leq \det(X)^{1/n}\}. \tag{10.18}$$

A standard approach when working with the determinant of a PSD matrix is to consider a semidefinite cone

$$\begin{pmatrix} X & Z \\ Z^T & \text{Diag}(Z) \end{pmatrix} \succeq 0 \tag{10.19}$$

where Z is a matrix of additional variables and where we intuitively identify $\text{Diag}(Z) = \{\lambda_1, \dots, \lambda_n\}$ with the eigenvalues of X . With this in mind, we are left with expressing the constraint

$$t \leq (\lambda_1 \cdots \lambda_n)^{1/n}. \tag{10.20}$$

This is easy to implement recursively using rotated quadratic cones when n is a power of 2; otherwise we need to round n up to the nearest power of 2 as in Listing 10.10. For example, $t \leq (\lambda_1 \lambda_2 \lambda_3 \lambda_4)^{1/4}$ is equivalent to

$$\lambda_1 \lambda_2 \geq y_1^2, \lambda_3 \lambda_4 \geq y_2^2, y_1 y_2 \geq t^2$$

while $t \leq (\lambda_1 \lambda_2 \lambda_3)^{1/3}$ can be achieved by writing $t \leq (t \lambda_1 \lambda_2 \lambda_3)^{1/4}$.

For further details and proofs see [BenTalN01] or [MOSEKApS12].

Listing 10.9: Approaching the determinant, see (10.19).

```
void det_rootn(Model::t M, int n, Variable::t X, Variable::t t)
{
    // Setup variables
    Variable::t Y = M->variable(Domain::inPSDCone(2 * n));

    // Setup Y = [X, Z; Z^T diag(Z)]
    Variable::t Y11 = Y->slice(new_array_ptr<int, 1>({0, 0}), new_array_ptr<int, 1>({n, n}));
    Variable::t Y21 = Y->slice(new_array_ptr<int, 1>({n, 0}), new_array_ptr<int, 1>({2 * n, n}));
    Variable::t Y22 = Y->slice(new_array_ptr<int, 1>({n, n}), new_array_ptr<int, 1>({2 * n, 2 * n}));

    M->constraint( Expr::sub(Y21->diag(), Y22->diag()), Domain::equalsTo(0.0) );
    M->constraint( Expr::sub(X, Y11), Domain::equalsTo(0.0) );

    // t^n <= (Z11*Z22*...*Znn)
    geometric_mean(M, Y22->diag(), t);
}
```

Listing 10.10: Bounding the geometric mean, see (10.20).

```
void geometric_mean(Model::t M, Variable::t x, Variable::t t)
{
    int n = (int) x->size();
    int l = (int) std::ceil(std::log(n) / std::log(2));
    int m = pow2(l) - n;

    Variable::t x0 =
        m == 0 ? x : Var::vstack(x, M->variable(m, Domain::greaterThan(0.0)));

    Variable::t z = x0;

    for (int i = 0; i < l - 1; ++i)
    {
        Variable::t xi = M->variable(pow2(l - i - 1), Domain::greaterThan(0.0));
        for (int k = 0; k < pow2(l - i - 1); ++k)
            M->constraint(Var::vstack(z->index(2 * k), z->index(2 * k + 1), xi->index(k)),
                Domain::inRotatedQCone());
        z = xi;
    }

    Variable::t t0 = M->variable(1, Domain::greaterThan(0.0));
    M->constraint(Var::vstack(z, t0), Domain::inRotatedQCone());

    M->constraint(Expr::sub(Expr::mul(std::pow(2, 0.5 * l), t), t0), Domain::equalsTo(0.0));

    for (int i = pow2(l - m); i < pow2(l); ++i)
        M->constraint(Expr::sub(x0->index(i), t), Domain::equalsTo(0.0));
}
```

10.5 Nearest Correlation Matrix Problem

A *correlation matrix* is a symmetric positive definite matrix with unit diagonal. This term has origins in statistics, since the matrix whose entries are the correlation coefficients of a sequence of random variables has all these properties.

In this section we study variants of the problem of approximating a given symmetric matrix A with correlation matrices:

- find the correlation matrix X nearest to A in the *Frobenius norm*,
- find an approximation of the form $D + X$ where D is a diagonal matrix with positive diagonal and X is a positive semidefinite matrix of low rank, using the combination of Frobenius and *nuclear norm*.

Both problems are related to *portfolio optimization*, where one can often have a matrix A that only approximates the correlations of stocks. For subsequent optimizations one would like to approximate A with a correlation matrix or, in the factor model, with $D + VV^T$ with VV^T of small rank.

10.5.1 Nearest correlation with the Frobenius norm

The Frobenius norm of a real matrix M is defined as

$$\|M\|_F = \left(\sum_{i,j} M_{i,j}^2 \right)^{1/2}$$

and with respect to this norm our optimization problem can be expressed simply as:

$$\begin{aligned} & \text{minimize} && \|A - X\|_F \\ & \text{subject to} && \mathbf{diag}(X) = e, \\ & && X \succeq 0. \end{aligned} \tag{10.21}$$

We can exploit the symmetry of A and X to get a compact vector representation. To this end we make use of the following mapping from a symmetric matrix to a flattened vector containing the (scaled) lower triangular part of the matrix:

$$\begin{aligned} \text{vec} : & \quad \mathbb{R}^{n \times n} \rightarrow \mathbb{R}^{n(n+1)/2} \\ \text{vec}(M) = & \quad (\alpha_{11}M_{11}, \alpha_{21}M_{21}, \alpha_{22}M_{22}, \dots, \alpha_{n1}M_{n1}, \dots, \alpha_{nn}M_{nn}) \\ \alpha_{ij} = & \quad \begin{cases} 1 & j = i \\ \sqrt{2} & j < i \end{cases} \end{aligned} \tag{10.22}$$

Note that $\|M\|_F = \|\text{vec}(M)\|_2$. The *Fusion* implementation of `vec` is as follows:

Listing 10.11: Implementation of function `vec` in (10.22).

```
Expression::t vec(Expression::t e)
{
    int N = e->getShape()->dim(0);
    int dim = N * (N + 1) / 2;

    auto msubi = new_array_ptr<int, 1>(dim);
    auto msubj = new_array_ptr<int, 1>(dim);
    auto mcof = new_array_ptr<double, 1>(dim);

    for (int i = 0, k = 0; i < N; ++i)
        for (int j = 0; j < i + 1; ++j, ++k)
        {
            (*msubi)[k] = k;
            (*msubj)[k] = i * N + j;
        }
}
```

```

    (*mcof) [k] = (i == j) ? 1.0 : std::sqrt(2.0);
}

Matrix::t S = Matrix::sparse(N * (N + 1) / 2, N * N, msubi, msubj, mcof);
return Expr::mul(S, Expr::reshape(e, N * N));
}

```

That leads to an optimization problem with both conic quadratic and semidefinite constraints:

$$\begin{aligned}
 & \text{minimize} && t \\
 & \text{subject to} && (t, \text{vec}(A - X)) \in \mathcal{Q}, \\
 & && \text{diag}(X) = e, \\
 & && X \succeq 0.
 \end{aligned} \tag{10.23}$$

Code example

Listing 10.12: Implementation of problem (10.23).

```

void nearestcorr( std::shared_ptr<ndarray<double, 2>> A)
{
    int N = A->size(0);

    // Create a model
    Model::t M = new Model("NearestCorrelation"); auto _M = finally([&]() { M->dispose(); });

    // Setting up the variables
    Variable::t X = M->variable("X", Domain::inPSDCone(N));
    Variable::t t = M->variable("t", 1, Domain::unbounded());

    // (t, vec(A-X)) \in Q
    M->constraint( Expr::vstack(t, vec(Expr::sub(A, X))), Domain::inQCone() );

    // diag(X) = e
    M->constraint(X->diag(), Domain::equalsTo(1.0));

    // Objective: Minimize t
    M->objective(ObjectiveSense::Minimize, t);

    // Solve the problem
    M->solve();

    // Get the solution values
    std::cout << "X = \n"; print_mat(std::cout, X->level());
    std::cout << "t = " << *(t->level()->begin()) << std::endl;
}

```

We use the following input

Listing 10.13: Input for the nearest correlation problem.

```

int N = 5;
auto A = new_array_ptr<double, 2>(
{ { 0.0, 0.5, -0.1, -0.2, 0.5},
  { 0.5, 1.25, -0.05, -0.1, 0.25},
  { -0.1, -0.05, 0.51, 0.02, -0.05},
  { -0.2, -0.1, 0.02, 0.54, -0.1},
  { 0.5, 0.25, -0.05, -0.1, 1.25}
});

```

The expected output is the following (small differences may apply):

```

X =
[ 1 0.500019 -0.0999999 -0.200001 0.500019]
[ 0.500019 1 -0.0499955 -0.0999915 0.249991]
[ -0.0999999 -0.0499955 1 0.0199975 -0.0499955]
[ -0.200001 -0.0999915 0.0199975 1 -0.0999915]
[ 0.500019 0.249991 -0.0499955 -0.0999915 1]

```

10.5.2 Nearest Correlation with Nuclear-norm Penalty

Next, we consider the approximation of A of the form $D + X$ where $D = \mathbf{diag}(w)$, $w \geq 0$ and $X \succeq 0$. We will also aim at minimizing the rank of X . This can be approximated by a relaxed linear objective penalizing the trace $\text{Tr}(X)$ (which in this case is the *nuclear norm* of X and happens to be the sum of its eigenvalues).

The combination of these constraints leads to a problem:

$$\begin{aligned} & \text{minimize} && \|X + \mathbf{diag}(w) - A\|_F + \gamma \text{Tr}(X), \\ & \text{subject to} && X \succeq 0, w \geq 0, \end{aligned}$$

where the parameter γ controls the tradeoff between the quality of approximation and the rank of X .

Exploit the mapping vec defined in (10.22) we can express this problem as:

$$\begin{aligned} & \text{minimize} && t + \gamma \text{Tr}(X) \\ & \text{subject to} && (t, \text{vec}(X + \mathbf{diag}(w) - A)) \in \mathcal{Q}, \\ & && X \succeq 0, w \geq 0. \end{aligned} \tag{10.24}$$

Code example

Listing 10.14: Implementation of problem (10.24).

```

void nearestcorr_nn(
    std::shared_ptr<ndarray<double, 2>> A,
    const std::vector<double> & gammas,
    std::vector<double> & res,
    std::vector<double> & rank)
{
    int N = A->size(0);

    Model::t M = new Model("NucNorm"); auto M_ = monty::finally([&]() { M->dispose(); });

    // Setup variables
    Variable::t t = M->variable("t", 1, Domain::unbounded());
    Variable::t X = M->variable("X", Domain::inPSDCone(N));
    Variable::t w = M->variable("w", N, Domain::greaterThan(0.0));

    // (t, vec(X + diag(w) - A)) in Q
    Expression::t D = Expr::mulElm( Matrix::eye(N), Var::repeat(w, 1, N) );
    M->constraint( Expr::vstack( t, vec(Expr::sub(Expr::add(X, D), A)) ), Domain::inQCone() );

    // Trace(X)
    auto TrX = Expr::sum(X->diag());

    for (int k = 0; k < gammas.size(); ++k)
    {
        // Objective: Minimize t + gamma*Tr(X)
        M->objective(ObjectiveSense::Minimize, Expr::add(t, Expr::mul(gammas[k], TrX)));
        M->solve();

        // Find the eigenvalues of X and approximate its rank
    }
}

```

```

auto d = new_array_ptr<double, 1>(N);
mosek::LinAlg::syev(MSK_UPLO_LO, N, X->level(), d);
int rnk = 0; for (int i = 0; i < N; ++i) if ((*d)[i] > 1e-6) ++rnk;

res[k] = (*(t->level()))[0];
rank[k] = rnk;
}
}

```

We feed **MOSEK** with the same input as in [Sec. 10.5.1](#). The problem is solved for a range of values γ values, to demonstrate how the penalty term helps achieve a low rank solution. To this extent we report both the rank of X and the residual norm $\|X + \mathbf{diag}(w) - A\|_F$.

```

gamma = 0.00, rank = 4.00, res = 0.31
gamma = 0.10, rank = 2.00, res = 0.43
gamma = 0.20, rank = 1.00, res = 0.51
gamma = 0.30, rank = 1.00, res = 0.53
gamma = 0.40, rank = 1.00, res = 0.56
gamma = 0.50, rank = 1.00, res = 0.60
gamma = 0.60, rank = 1.00, res = 0.68
gamma = 0.70, rank = 1.00, res = 0.80
gamma = 0.80, rank = 1.00, res = 1.06
gamma = 0.90, rank = 0.00, res = 1.13
gamma = 1.00, rank = 0.00, res = 1.13

```

10.6 Semidefinite Relaxation of MIQCQO Problems

In this case study we will discuss a fairly common application for Semidefinite Optimization: to define a continuous semidefinite relaxation of a mixed-integer quadratic optimization problem. This section is based on the method by Park and Boyd [\[PB15\]](#).

We will focus on problems of the form:

$$\begin{aligned} & \text{minimize} && x^T P x + 2q^T x \\ & \text{subject to} && x \in \mathbb{Z}^n \end{aligned} \quad (10.25)$$

where $q \in \mathbb{R}^n$ and $P \in \mathcal{S}_+^{n \times n}$ is positive semidefinite. There are many important problems that can be reformulated as (10.25), for example:

- *integer least squares*: minimize $\|Ax - b\|_2^2$ subject to $x \in \mathbb{Z}^n$,
- *closest vector problem*: minimize $\|v - z\|_2$ subject to $z \in \{Bx \mid x \in \mathbb{Z}^n\}$.

Following [\[PB15\]](#), we can derive a relaxed continuous model. We first relax the integrality constraint

$$\begin{aligned} & \text{minimize} && x^T P x + 2q^T x \\ & \text{subject to} && x_i(x_i - 1) \geq 0 \quad i = 1, \dots, n. \end{aligned}$$

The last constraint is still non-convex. We introduce a new variable $X \in \mathbb{R}^{n \times n}$, such that $X = x \cdot x^T$. This allows us to write an equivalent formulation:

$$\begin{aligned} & \text{minimize} && \text{Tr}(PX) + 2q^T x \\ & \text{subject to} && \mathbf{diag}(X) \geq x, \\ & && X = x \cdot x^T. \end{aligned}$$

To get a conic problem we relax the last constraint and apply the Schur complement. The final relaxation follows:

$$\begin{aligned} & \text{minimize} && \text{Tr}(PX) + 2q^T x \\ & \text{subject to} && \mathbf{diag}(X) \geq x, \\ & && \begin{bmatrix} X & x \\ x^T & 1 \end{bmatrix} \in \mathcal{S}_+^{n+1}. \end{aligned} \quad (10.26)$$

Fusion Implementation

Implementing model (10.26) in *Fusion* is very simple. We assume the input n , P and q . Then we proceed creating the optimization model

```
Model::t M = new Model();
```

The important step is to define a single PSD variable

$$Z = \begin{bmatrix} X & x \\ x^T & 1 \end{bmatrix} \in \mathcal{S}_+^{n+1}.$$

Our code will create Z and two slices that correspond to X and x :

```
Variable::t Z = M->variable("Z", n + 1, Domain::inPSDCone());

Variable::t X = Z->slice(new_array_ptr<int, 1>({0, 0}), new_array_ptr<int, 1>({n, n}));
Variable::t x = Z->slice(new_array_ptr<int, 1>({0, n}), new_array_ptr<int, 1>({n, n + 1}));
```

Then we define the constraints:

```
M->constraint( Expr::sub(X->diag(), x), Domain::greaterThan(0.) );
M->constraint( Z->index(n, n), Domain::equalsTo(1.) );
```

The objective function uses several available linear expressions:

```
M->objective( ObjectiveSense::Minimize, Expr::add(
    Expr::sum( Expr::mulElm( P, X ) ),
    Expr::mul( 2.0, Expr::dot(x, q) )
) );
```

Note that the *trace* operator is not directly available in *Fusion*, but it can easily be defined from scratch.

Complete code

Listing 10.15: *Fusion* implementation of model (10.26).

```
Model::t miqcqp_sdo_relaxation(int n, Matrix::t P, const std::shared_ptr<ndarray<double, 1>> &q) {
    Model::t M = new Model();

    Variable::t Z = M->variable("Z", n + 1, Domain::inPSDCone());

    Variable::t X = Z->slice(new_array_ptr<int, 1>({0, 0}), new_array_ptr<int, 1>({n, n}));
    Variable::t x = Z->slice(new_array_ptr<int, 1>({0, n}), new_array_ptr<int, 1>({n, n + 1}));

    M->constraint( Expr::sub(X->diag(), x), Domain::greaterThan(0.) );
    M->constraint( Z->index(n, n), Domain::equalsTo(1.) );

    M->objective( ObjectiveSense::Minimize, Expr::add(
        Expr::sum( Expr::mulElm( P, X ) ),
        Expr::mul( 2.0, Expr::dot(x, q) )
    ) );

    return M;
}
```

Numerical Examples

We present now some simple numerical experiments for the integer least squares problem:

$$\begin{aligned} & \text{minimize} && \|Ax - b\|_2^2 \\ & \text{subject to} && x \in \mathbb{Z}^n. \end{aligned} \quad (10.27)$$

It corresponds to the problem (10.25) with $P = A^T A$ and $q = -A^T b$. Following [PB15] we will generate the input data by taking all entries of A from the normal distribution $\mathcal{N}(0, 1)$ and setting $b = Ac$ where c comes from the uniform distribution on $[0, 1]$.

We implement the linear algebra operations using the `LinAlg` module available in **MOSEK**.

An integer rounding `xRound` of the solution to (10.26) is a feasible integer solution to (10.27). We can compare it to the actual optimal integer solution `xOpt`, whenever the latter is available. Of course it is very simple to formulate the integer least squares problem in *Fusion*:

```
Model::t int_least_squares(int n, Matrix::t A, const std::shared_ptr<ndarray<double, 1>> & b) {
    Model::t M = new Model();

    Variable::t x = M->variable("x", n, Domain::integral(Domain::unbounded()));
    Variable::t t = M->variable("t", 1, Domain::unbounded());

    M->constraint( Expr::vstack(t, Expr::sub(Expr::mul(A, x), b)), Domain::inQCone() );
    M->objective( ObjectiveSense::Minimize, t );

    return M;
}
```

All that remains is to compare the values of the objective function $\|Ax - b\|_2$ for the two solutions.

Listing 10.16: The comparison of two solutions.

```
// problem dimensions
int n = 20;
int m = 2 * n;

auto c = new_array_ptr<double, 1>(n);
auto A = new_array_ptr<double, 1>(n * m);
auto P = new_array_ptr<double, 1>(n * n);
auto b = new_array_ptr<double, 1>(m);
auto q = new_array_ptr<double, 1>(n);

std::generate(A->begin(), A->end(), std::bind(normal_distr, generator));
std::generate(c->begin(), c->end(), std::bind(unif_distr, generator));
std::fill(b->begin(), b->end(), 0.0);
std::fill(q->begin(), q->end(), 0.0);

// P = A^T A
syrk(MSK_UPLO_LO, MSK_TRANSPOSE_YES,
     n, m, 1.0, A, 0., P);
for (int j = 0; j < n; j++) for (int i = j + 1; i < n; i++) (*P)[i * n + j] = (*P)[j * n + i]
↪ + i];

// q = -P c, b = A c
gemv(MSK_TRANSPOSE_NO, n, n, -1.0, P, c, 0., q);
gemv(MSK_TRANSPOSE_NO, m, n, 1.0, A, c, 0., b);

// Solve the problems
{
    Model::t M = miqcqp_sdo_relaxation(n, Matrix::dense(n, n, P), q);
    Model::t Mint = int_least_squares(n, Matrix::dense(n, m, A->transpose(), b);
```

```

M->solve();
Mint->solve();

auto xRound = M->getVariable("Z")->
    slice(new_array_ptr<int, 1>({0, n}), new_array_ptr<int, 1>({n, n + 1}))->
    level();
for (int i = 0; i < n; i++) (*xRound)[i] = round((*xRound)[i]);
auto yRound = new_array_ptr<double, 1>(m);
auto xOpt = Mint->getVariable("x")->level();
auto yOpt = new_array_ptr<double, 1>(m);
std::copy(b->begin(), b->end(), yRound->begin());
std::copy(b->begin(), b->end(), yOpt->begin());
gemv(MSK_TRANSPOSE_NO, m, n, 1.0, A, xRound, -1.0, yRound);           // Ax_round=b
gemv(MSK_TRANSPOSE_NO, m, n, 1.0, A, xOpt, -1.0, yOpt);             // Ax_opt=b

std::cout << M->getSolverDoubleInfo("optimizerTime") << " " << Mint->getSolverDoubleInfo(
    "optimizerTime") << "\n";
double valRound, valOpt;
dot(m, yRound, yRound, valRound); dot(m, yOpt, yOpt, valOpt);
std::cout << sqrt(valRound) << " " << sqrt(valOpt) << "\n";
}

```

Experimentally the objective value for `xRound` approximates the optimal solution with a factor of 1.1-1.4. We refer to [PB15] for a more involved iterative rounding procedure, producing integer solutions of even better quality, and for a detailed discussion of test results.

10.7 SUDOKU

SUDOKU is a famous simple yet mind-blowing game. The objective is to fill a 9×9 grid with digits so that each column, each row, and each of the nine 3×3 sub-grids that compose the grid (also called *boxes*, *blocks*, *regions*, or *sub-squares*) contains all of the digits from 1 to 9. For more information see <http://en.wikipedia.org/wiki/Sudoku>. Here is a simple example:

				4				
	5	8			3			
	1		2	8		9		
	7	3	1			8	4	
	4	1			9	2	7	
		4		6	5		8	
			4			1	6	
				9				

A simple unsolved Sudoku

3	2	9	5	4	7	6	1	8
6	5	8	9	1	3	4	2	7
4	1	7	2	8	6	9	5	3
9	7	3	1	5	2	8	4	6
5	6	2	8	7	4	3	9	1
8	4	1	6	3	9	2	7	5
1	9	4	3	6	5	7	8	2
7	3	5	4	2	8	1	6	9
2	8	6	7	9	1	5	3	4

The solution

In a more general setting we are given a grid of dimension $n \times n$, with $n = m^2$, $m \in \mathbb{N}$. Each cell (i, j) must be filled with an integer $y_{ij} \in [1, n]$. Along each row and each column there must be no repetitions. No repetitions are allowed also in each sub-grid with corners $\{(mt, ml), (m(t+1)-1, m(l+1)-1)\}$, for $t, l = 0, \dots, m-1$ (we index cells from $(0, 0)$).

In general, each SUDOKU instance comes with a set F of predetermined values which:

- reduce the complexity of the game by removing symmetries and guiding the initial moves of the player;

- ensure that there will be a unique solution.

We represent the set F as list of triplets (i, j, v) , meaning that the cell (i, j) contains the value v .

Note that SUDOKU is a **feasibility** problem. A typical Integer Programming formulation is straightforward: let x_{ijk} be a binary variable that takes value 1 if k is written in cell (i, j) . Then we look for a feasible solution of a system of constraints given below.

SUDOKU is a typical assignment problem. Its constraints are commonly found in optimization problems concerning scheduling or resource allocation. SUDOKU has also been a nice problem to fiddle with for many researchers in the optimization community. Indeed, its simple structure and the easy way in which the results can be tested make it a perfect test problem.

We will approach SUDOKU as a standard integer linear program, and we will show how easily and elegantly it can be implemented in *Fusion*.

Mathematical Formulation

In this section we formulate SUDOKU as a mixed-integer linear optimization problem. Let's introduce a binary variable x_{ijk} that takes value 1 if k is written in the cell (i, j) , or 0 otherwise. We first ask that for each cell exactly one digit is selected:

$$\sum_{k=0}^{n-1} x_{ijk} = 1, \quad i, j = 0, \dots, n-1. \quad (10.28)$$

Similar constraints can be used to force each digit to appear only once in each row or column:

$$\begin{aligned} \sum_{i=0}^{n-1} x_{ijk} &= 1, & j, k &= 0, \dots, n-1, \\ \sum_{j=0}^{n-1} x_{ijk} &= 1, & i, k &= 0, \dots, n-1. \end{aligned} \quad (10.29)$$

To force a digit to appear only once in each sub-grid we can use the following

$$\sum_{i=0}^{m-1} \sum_{j=0}^{m-1} x_{(i+tm)(j+tl)k} = 1 \quad k = 0, \dots, n-1 \text{ and } t, l = 0, \dots, m-1 \quad (10.30)$$

If a cell (i, j) has a predetermined value, i.e. $(i, j, k) \in F$ then we set

$$x_{ijk} = 1.$$

Summarizing, and considering that there is no objective function to minimize, the optimization model for the SUDOKU problem takes the form

$$\begin{aligned} &\min 0 \\ &\text{s.t.} \\ &\sum_{i=0}^{n-1} x_{ijk} = 1, & j, k &= 0, \dots, n-1, \\ &\sum_{j=0}^{n-1} x_{ijk} = 1, & i, k &= 0, \dots, n-1, \\ &\sum_{k=0}^{n-1} x_{ijk} = 1, & i, j &= 0, \dots, n-1, \\ &\sum_{i=0}^{m-1} \sum_{j=0}^{m-1} x_{(i+tm)(j+tl)k} = 1, & k &= 0, \dots, n-1 \text{ and } \\ & & & t, l = 0, \dots, m-1, \\ &x_{ijk} = 1, & \forall (i, j, k) \in F. \end{aligned} \quad (10.31)$$

Implementation with *Fusion*

The implementation in *Fusion* is straightforward. First, we represent the variable x using a three dimensional *Fusion* variable:

```
Variable::t X = M->variable("X", new_array_ptr<int, 1>({n, n, n}), Domain::binary());
```

Then we can define constraints (10.28) and (10.29) simply using the *Expr.sum* operator, that allows to sum the elements of an expression (in this case of the variable itself) along arbitrary dimensions. The code reads:

```
//each value only once per dimension
for (int d = 0; d < m; d++)
    M->constraint( Expr::sum(X, d), Domain::equalsTo(1.) );
```

The last set of constraints (10.30), i.e. the sum over block, needs a little more effort: we must loop over all blocks and select the proper slice:

```
//each number must appear only once in a block
for (int k = 0; k < n; k++)
    for (int i = 0; i < m; i++)
        for (int j = 0; j < m; j++)
            M->constraint( Expr::sum( X->slice( new_array_ptr<int, 1>({i * m, j * m, k}),
                                                new_array_ptr<int, 1>({(i + 1)*m, (j + 1)*m, k + 1}
↪) ) ),
                        Domain::equalsTo(1.) );
```

To set the triplets given in the set F we can use the *Variable.pick* method that returns a one dimensional view of an arbitrary set of elements of the variable.

```
auto fixed = std::shared_ptr< ndarray<int, 2> >( new ndarray<int, 2>( shape(nfixed, 3) ) );

for (int i = 0; i < nfixed; i++)
    for (int d = 0; d < m; d++)
        (*fixed)(i, d) = (*hr_fixed)(i, d) - 1;

M->constraint( X->pick( fixed ), Domain::equalsTo(1.0) );
```

SUDOKU: the complete example code.

The complete code for the SUDOKU problem is shown in Listing 10.17.

Listing 10.17: *Fusion* implementation to solve SUDOKU.

```
#include <iostream>
#include <sstream>
#include <cmath>

#include "fusion.h"

using namespace mosek::fusion;
using namespace monty;

void print_solution(int n, Variable::t X)
{
    using namespace std;

    cout << "\n";
    int m( std::sqrt(n) );
    for (int i = 0; i < n; i++)
    {
        stringstream ss;

        for (int j = 0; j < n; j++)
        {
```

```

    if (j % m == 0) ss << " |";

    for (int k = 0; k < n; k++)
    {
        auto x = X->index(new_array_ptr<int, 1>({i, j, k}))->level();
        if ( (*x)[0] > 0.5 )
        {
            ss << " " << (k + 1);
            break;
        }
    }
    cout << ss.str() << " |";

    cout << "\n";
    if ((i + 1) % m == 0)
        cout << "\n";
}
}

int main(int argc, char ** argv)
{

    int m = 3;
    int n = m * m;

    //fixed cells in human readable (i.e. 1-based) format
    auto hr_fixed = new_array_ptr<int, 2>(
    { {1, 5, 4},
      {2, 2, 5}, {2, 3, 8}, {2, 6, 3},
      {3, 2, 1}, {3, 4, 2}, {3, 5, 8}, {3, 7, 9},
      {4, 2, 7}, {4, 3, 3}, {4, 4, 1}, {4, 7, 8}, {4, 8, 4},
      {6, 2, 4}, {6, 3, 1}, {6, 6, 9}, {6, 7, 2}, {6, 8, 7},
      {7, 3, 4}, {7, 5, 6}, {7, 6, 5}, {7, 8, 8},
      {8, 4, 4}, {8, 7, 1}, {8, 8, 6},
      {9, 5, 9}
    }
    );

    int nfixed = hr_fixed->size() / m;

    Model::t M = new Model("SUDOKU"); auto _M = finally([&]() { M->dispose(); });

    M->setLogHandler([ = ](const std::string & msg) { std::cout << msg << std::flush; });

    Variable::t X = M->variable("X", new_array_ptr<int, 1>({n, n, n}), Domain::binary());

    //each value only once per dimension
    for (int d = 0; d < m; d++)
        M->constraint( Expr::sum(X, d), Domain::equalsTo(1.) );

    //each number must appear only once in a block
    for (int k = 0; k < n ; k++)
        for (int i = 0; i < m ; i++)
            for (int j = 0; j < m ; j++)
                M->constraint( Expr::sum( X->slice( new_array_ptr<int, 1>({i * m, j * m, k}),
                                                    new_array_ptr<int, 1>({(i + 1)*m, (j + 1)*m, k + 1}
                                                    ↪ ) ) ),
                                Domain::equalsTo(1.) );

    auto fixed = std::shared_ptr< ndarray<int, 2> >( new ndarray<int, 2>( shape(nfixed, 3) ) );

    for (int i = 0; i < nfixed; i++)

```

```

    for (int d = 0; d < m; d++)
        (*fixed)(i, d) = (*hr_fixed)(i, d) - 1;

M->constraint( X->pick( fixed ) , Domain::equalsTo(1.0) ) ;

M->solve();

//print the solution, if any...
if ( M->getPrimalSolutionStatus() == SolutionStatus::Optimal ||
    M->getPrimalSolutionStatus() == SolutionStatus::NearOptimal)
    print_solution(n, X);
else
    std::cout << "No solution found!\n";

return 0;
}

```

The problem instance corresponding to [Fig. 10.7](#) is hard-coded for the sake of simplicity. It will produce the following output

```

10.8 Multiprocessor Scheduling

In this case study we consider a simple scheduling problem in which a set of jobs must be assigned to a set of identical machines. We want to minimize the makespan of the overall processing, i.e. the latest machine termination time.

The main aims of this case study are

- to show how to define a Integer Linear Programming model,
- to take advantage of *Fusion* operators to compactly express sets of constraints,
- to provide the solver with an incumbent integer feasible solution.

Mathematical formulation

We are given a set of jobs J with $|J| = n$ to be assigned to a set M of identical machines with $|M| = m$. Each job $j \in J$ has a processing time $T_j > 0$ and can be assigned to any machine. Our aim is to find the job scheduling that minimizes the overall makespan, i.e. the maximum completion time among all machines.

Formally, we introduce a binary variable x_{ij} that takes value 1 if the job j is assigned to the machine i , zero otherwise. The only constraint we need to set is the requirement that a job must be assigned to a single machine. The optimization model takes the following form:

$$\begin{aligned} & \min \max_{i \in M} \sum_{j \in J} T_j x_{ij} \\ \text{s.t. } & \sum_{i \in M} x_{ij} = 1, & j \in J, \\ & x_{ij} \in \{0, 1\} & \forall i \in M, j \in J. \end{aligned} \quad (10.32)$$

Model (10.32) can be easily transformed into an integer linear programming model as follows:

$$\begin{aligned} & \min t \\ \text{s.t. } & \sum_{i \in M} x_{ij} = 1, & j \in J, \\ & t \geq \sum_{j \in J} T_j x_{ij}, & i \in M, \\ & x_{ij} \in \{0, 1\}, & \forall i \in M, j \in J. \end{aligned} \quad (10.33)$$

The implementation of this model in *Fusion* is straightforward:

```
Model::t M = new Model("Multi-processor scheduling"); auto _M = finally([&]() { M->dispose();
↪ });

Variable::t x = M->variable("x", new_array_ptr<int, 1>({m, n}), Domain::binary());
Variable::t t = M->variable("t", 1, Domain::unbounded());
```

```
M->constraint( Expr::sum(x, 0), Domain::equalsTo(1.) );
M->constraint( Expr::sub( Var::repeat(t, m), Expr::mul(x, T) ), Domain::greaterThan(0.) );

M->objective( ObjectiveSense::Minimize, t );
```

Most of the code is self-explanatory. The only critical point is

```
M->constraint( Expr::sub( Var::repeat(t, m), Expr::mul(x, T) ), Domain::greaterThan(0.) );
```

that implements the set of constraints

$$t \geq \sum_{j \in J} T_j x_{ij}, \quad i \in M.$$

To fit in *Fusion* we restate the constraints as

$$t - \sum_{j \in J} T_j x_{ij} \geq 0, \quad i \in M,$$

which corresponds in matrix form to

$$t\mathbf{1} - xT \geq 0. \quad (10.34)$$

The function `Var.repeat` creates a vector of length m , as required for (10.34). The same result can be obtained via matrix multiplication, i.e. using `Expr.mul`, but in this particular case `Var.repeat` is faster as it only performs a logical operation.

Longest Processing Time first rule (LPT)

The multiprocessor scheduling is known to be an NP-complete problem (see [GJ79]). Nevertheless there are effective heuristics, with provable worst case bounds, that are able to provide a good integer solution quickly. In particular, we will use the so-called *Longest Processing Time first* rule (LPT, proposed in [Gra69]).

The informal algorithm sketch is the following:

- while M is not empty do
 - let k be the machine with the smallest load so far,
 - let i be the job in M with the longest completion time,
 - assign job i to machine k ,
 - update the load of machine k ,
 - remove i from M .

This simple algorithm is a $\frac{1}{3}(4 - \frac{1}{m})$ approximation. So for $m = 1$ we get the optimal solution (indeed there is no choice with a single machine); for $m \rightarrow \infty$ the approximation factor is no worse than $4/3$ (again see [Gra69]).

A simple implementation is given below.

```
//LPT heuristic
auto schedule = std::shared_ptr<ndarray<double, 1>>(new ndarray<double, 1>(m, 0.));
auto init = std::shared_ptr<ndarray<double, 1>>(new ndarray<double, 1>(n * m, 0.));

for (int i = 0; i < n; i++)
{
    auto pos = std::distance(schedule->begin(), std::min_element(schedule->begin(), schedule->
    end()));
    (*schedule)[pos] += (*T)[i];
    (*init)[pos * n + i] = 1;
}
```

An efficient implementation of the LPT rule is beyond the scope of this section. The important part is that the scheduling produced by the LPT algorithm can be used as incumbent solution for the **MOSEK** mixed-integer linear programming solver. The availability of an integer feasible solution can significantly improve the performance of the solver.

To input the solution we only need to use the `Variable.setLevel` method, as shown below

```
x->setLevel(init);
```

We can test the program with and without providing the initial LPT solution. Our random datasets consists of a mix of tasks with long and short processing times and we accept a solution at relative optimality tolerance 0.01. Some results are shown in the table below.

Table 10.1: Sample test results for the makespan problem.

n	m	long tasks	short tasks	No LPT	With LPT
1000	8	20%	80%	13.36s	1.23s
1000	8	80%	20%	1.35s	1.24s
100	12	20%	80%	16.37s	0.11s
100	12	80%	20%	16.62s	10.01s
20	20	0%	100%	10.38s	21.88s

We can see that depending on the structure and parameters of the problem it may pay off to provide an initial LPT solution. Therefore it is always recommended to test the mixed-integer solver with different settings to find the most efficient setup for a given problem.

Listing 10.18: Complete code for the LPT scheduling example.

```
#include <iostream>
#include <random>
#include <sstream>

#include "fusion.h"

using namespace mosek::fusion;
using namespace monty;

int main(int argc, char** argv)
{
    double lb = 1.0;           //Bounds for the length of a short task
    double ub = 5.;

    int    n = 30;             //Number of tasks
    int    m = 6;              //Number of processors

    double sh = 0.8;           //The proportion of short tasks
    int    n_short = (int)(sh * n);
    int    n_long = n - n_short;

    auto gen = std::bind(std::uniform_real_distribution<double>(lb, ub), std::mt19937(0));

    auto T = std::shared_ptr<ndarray<double, 1>>(new ndarray<double, 1>(n));
    for (int i = 0; i < n_short; i++) (*T)[i] = gen();
    for (int i = n_short; i < n; i++) (*T)[i] = 20 * gen();
    std::sort(T->begin(), T->end(), std::greater<double>());

    Model::t M = new Model("Multi-processor scheduling"); auto _M = finally([&]() { M->dispose();
    ↪ });

    Variable::t x = M->variable("x", new_array_ptr<int, 1>({m, n}), Domain::binary());
    Variable::t t = M->variable("t", 1, Domain::unbounded());
```

```

M->constraint( Expr::sum(x, 0), Domain::equalTo(1.) );
M->constraint( Expr::sub( Var::repeat(t, m), Expr::mul(x, T) ), Domain::greaterThan(0.) );

M->objective( ObjectiveSense::Minimize, t );

//LPT heuristic
auto schedule = std::shared_ptr<ndarray<double, 1>>(new ndarray<double, 1>(m, 0.));
auto init = std::shared_ptr<ndarray<double, 1>>(new ndarray<double, 1>(n * m, 0.));

for (int i = 0; i < n; i++)
{
    auto pos = std::distance(schedule->begin(), std::min_element(schedule->begin(), schedule->
↪end()));
    (*schedule)[pos] += (*T)[i];
    (*init)[pos * n + i] = 1;
}

//Comment this line to switch off feeding in the initial LPT solution
x->setLevel(init);

M->setLogHandler([ = ](const std::string & msg) { std::cout << msg << std::flush; } );

M->setSolverParam("mioTolRelGap", .01);
M->solve();

std::cout << "initial solution: \n";
for (int i = 0; i < m; i++)
{
    std::cout << "M " << i << " [";
    for (int y = 0; y < n; y++)
        std::cout << int( (*init)[i * n + y] ) << ", ";
    std::cout << "]\n";
}

std::cout << "MOSEK solution:\n";
for (int i = 0; i < m; i++)
{
    std::cout << "M " << i << " [";
    for (int y = 0; y < n; y++)
        std::cout << int((x->index(i, y)->level()))[0] << ", ";
    std::cout << "]\n";
}

return 0;
}

```

10.9 Travelling Salesman Problem (TSP)

The *Travelling Salesman Problem* is one of the most famous and studied problems in combinatorics and integer optimization. In this case study we shall:

- show how to compactly define a model with *Fusion*;
- implement an iterative algorithm that solves a sequence of optimization problems;
- modify an optimization problem by adding more constraints;
- show how to access the solution of an optimization problem.

The material presented in this section draws inspiration from [Pat03].

In a TSP instance we are given a directed graph $G = (N, A)$, where N is the set of nodes and A is the set of arcs. To each arc $(i, j) \in A$ corresponds a nonnegative cost c_{ij} . The goal is to find a minimum cost *Hamilton cycle* in G , that is a closed tour passing through each node exactly once. For example, consider the small directed graph in Fig. 10.6.

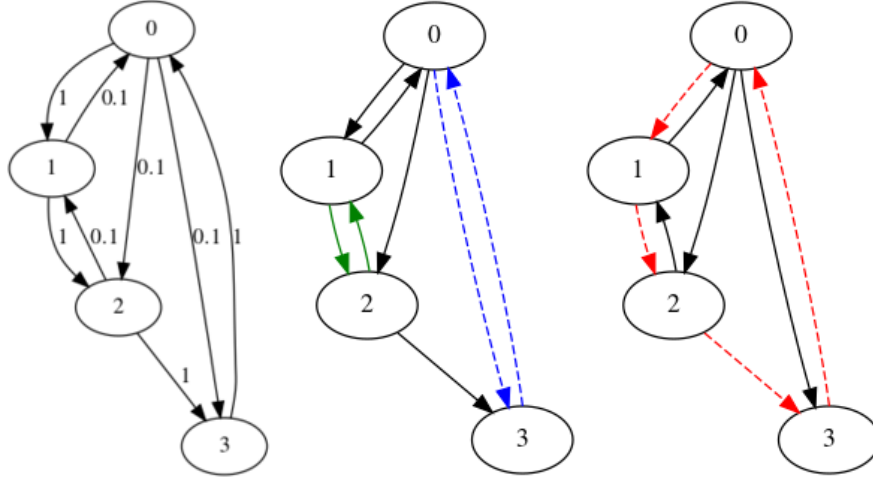

Fig. 10.6: (Left) a directed graph with costs. (Middle) The minimum cycle cover found in the first iteration. (Right) The minimum cost travelling salesman tour.

Its corresponding adjacency and cost matrices A and c are:

$$A = \begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}, \quad c = \begin{bmatrix} 0 & 1 & 0.1 & 0.1 \\ 0.1 & 0 & 1 & 0 \\ 0 & 0.1 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}.$$

Typically, the problem is modelled introducing a set of binary variables x_{ij} such that

$$x_{ij} = \begin{cases} 0 & \text{if arc } (i, j) \text{ is in the tour,} \\ 1 & \text{otherwise.} \end{cases}$$

Now we can introduce the following simple model:

$$\begin{aligned} \min \quad & \sum_{i,j} c_{ij} x_{ij} \\ \text{subject to} \quad & \sum_i x_{ij} = 1 \quad \forall j = 1, \dots, n, \\ & \sum_j x_{ij} = 1 \quad \forall i = 1, \dots, n, \\ & x_{ij} \leq A_{ij} \quad \forall i, j, \\ & x_{ij} \in \{0, 1\} \quad \forall i, j. \end{aligned} \tag{10.35}$$

It describes the constraint that every vertex has exactly one incoming and one outgoing arc in the tour, and that only arcs present in the graph can be chosen. Problem (10.35) can be easily implemented in *Fusion*:

```
Model::t M = new Model();
auto M_ = finally([&](){ M->dispose(); });

auto x = M->variable(new_array_ptr<int>, 1>({n, n}), Domain::binary());

M->constraint(Expr::sum(x, 0), Domain::equalsTo(1.0));
M->constraint(Expr::sum(x, 1), Domain::equalsTo(1.0));
M->constraint(x, Domain::lessThan( A ));

M->objective(ObjectiveSense::Minimize, Expr::dot(C, x));
```

Note in particular how:

- we can sum over rows and/or columns using the `Expr.sum` function;
- we use `Expr.dot` to compute the objective function.

The solution to problem (10.35) is not necessarily a closed tour. In fact (10.35) models another problem known as *minimum cost cycle cover*, whose solution may consist of more than one cycle. In our example we get the solution depicted in Fig. 10.6, i.e. there are two loops, namely $0 \rightarrow 3 \rightarrow 0$ and $1 \rightarrow 2 \rightarrow 1$.

A solution to (10.35) solves the TSP problem if and only if it consists of a single cycle. One classical approach ensuring this is the so-called *subtour elimination*: once we found a solution of (10.35) composed of at least two cycles, we add constraints that explicitly avoid that particular solution:

$$\sum_{(i,j) \in c} x_{ij} \leq |c| - 1 \quad \forall c \in C. \quad (10.36)$$

Thus the problem we want to solve at each step is

$$\begin{aligned} \min \quad & \sum_{i,j} c_{ij} x_{ij} \\ \text{subject to} \quad & \sum_i x_{ij} = 1 \quad \forall j = 1, \dots, n, \\ & \sum_j x_{ij} = 1 \quad \forall i = 1, \dots, n, \\ & x_{ij} \leq A_{ij} \quad \forall i, j, \\ & x_{ij} \in \{0, 1\} \quad \forall i, j, \\ & \sum_{(i,j) \in c} x_{ij} \leq |c| - 1 \quad \forall c \in C, \end{aligned} \quad (10.37)$$

where C is the set of cycles in all the cycle covers we have seen so far. The overall solution scheme is the following:

1. set C as the empty set,
2. solve problem (10.37),
3. **if** x has only one cycle **stop**,
4. **else** add the cycles of x to C and **goto** 2.

Cycle detection is a fairly easy task and we omit the procedure here for the sake of simplicity. Now we show how to add a constraint for each cycle. Since we have the list of arcs, and each one corresponds to a variable x_{ij} , we can use the function `Variable.pick` to compactly define constraints of the form (10.36):

```
for (auto c : cycles)
{
    int csize = c.size();

    auto tmp = std::shared_ptr<monty::ndarray<int, 2>>(new ndarray<int, 2>( shape(csize, 2) ));
    for (auto i = 0; i < csize; ++i)
    {
        (*tmp)(i, 0) = std::get<0>(c[i]);
        (*tmp)(i, 1) = std::get<1>(c[i]);
    }

    M->constraint(Expr::sum(x->pick(tmp)), Domain::lessThan( 1.0 * csize - 1 ));
}
```

Executing our procedure will yield the following output:

```
it #1 - solution cost: 2.200000

cycles:
[0,3] - [3,0] -
[1,2] - [2,1] -

it #2 - solution cost: 4.000000
```

```

cycles:
[0,1] - [1,2] - [2,3] - [3,0] -

solution:
0  1  0  0
0  0  1  0
0  0  0  1
1  0  0  0

```

Thus we first discover the two-cycle solution; then the second iteration is forced not to include those cycles, and a new solution is located. This time it consists of one loop, and as expected the cost is higher. The solution is depicted in [Fig. 10.6](#).

Formulation (10.37) can be improved in some cases by exploiting the graph structure. Some simple tricks follow.

Self-loops

Self-loops are never part of a TSP tour. Typically self-loops are removed by penalizing them with a huge cost c_{ii} . Although this works in practice, it is more advisable to just fix the corresponding variables to zero, i.e.

$$x_{ii} = 0 \quad \forall i = 1, \dots, n. \quad (10.38)$$

This removes redundant variables, and avoids unnecessarily large coefficients that can negatively affect the solver.

Constraints (10.38) are easily implemented as follows:

```
M->constraint(x->diag(), Domain::equalsTo(0.));
```

Two-arc loops removal

In networks with more than two nodes two-loop arcs can also be ignored. They are simple to detect and their number is of the same order as the size of the graph. The constraints we need to add are:

$$x_{ij} + x_{ji} \leq 1 \quad \forall i, j = 1, \dots, n. \quad (10.39)$$

Constraints (10.39) are easily implemented as follows:

```
M->constraint(Expr::add(x, x->transpose()), Domain::lessThan(1.0));
```

The complete working example

Listing 10.19: The complete code for the TSP examples.

```

template<typename MT>
void tsp(int n, MT A, MT C, bool remove_1_hop_loops, bool remove_2_hop_loops)
{
    Model::t M = new Model();
    auto M_ = finally([&]() { M->dispose(); });

    auto x = M->variable(new_array_ptr<int>, 1>({n, n}), Domain::binary());

    M->constraint(Expr::sum(x, 0), Domain::equalsTo(1.0));
    M->constraint(Expr::sum(x, 1), Domain::equalsTo(1.0));
    M->constraint(x, Domain::lessThan( A ));
}

```

```

M->objective(ObjectiveSense::Minimize, Expr::dot(C, x));

if (remove_1_hop_loops)
    M->constraint(x->diag(), Domain::equalsTo(0.));

if (remove_2_hop_loops)
    M->constraint(Expr::add(x, x->transpose()), Domain::lessThan(1.0));

int it = 0;
while (true)
{
    M->solve();
    it++;

    typedef std::vector< std::tuple<int, int> > cycle_t;
    std::list< cycle_t > cycles;

    for (int i = 0; i < n; i++)
        for (int j = 0; j < n; j++)
        {
            if ( ( *(x->level()) )[i * n + j] <= 0.5 )
                continue;

            bool found = false;
            for (auto && c : cycles)
            {
                for (auto && cc : c)
                {
                    if ( i == std::get<0>(cc) || i == std::get<1>(cc) ||
                        j == std::get<0>(cc) || j == std::get<1>(cc) )
                    {
                        c.push_back( std::make_tuple(i, j) );
                        found = true;
                        break;
                    }
                }
            }
            if (found) break;
        }

        if (!found)
            cycles.push_back(cycle_t(1, std::make_tuple(i, j)));
    }

    std::cout << "Iteration " << it << "\n";
    for (auto c : cycles) {
        for (auto cc : c)
            std::cout << "(" << std::get<0>(cc) << "," << std::get<1>(cc) << ") ";
        std::cout << "\n";
    }

    if (cycles.size() == 1) break;

    for (auto c : cycles)
    {
        int csize = c.size();

        auto tmp = std::shared_ptr<monty::ndarray<int, 2> >(new ndarray<int, 2>( shape(csize, 2) ));
        for (auto i = 0; i < csize; ++i)
        {
            (*tmp)(i, 0) = std::get<0>(c[i]);

```

```

        (*tmp)(i, 1) = std::get<1>(c[i]);
    }

    M->constraint(Expr::sum(x->pick(tmp)), Domain::lessThan( 1.0 * csize - 1 ));
}
}
try {
    std::cout << "Solution\n";
    for (int i = 0; i < n; i++) {
        for (int j = 0; j < n; j++)
            std::cout << (int) (*(x->level()))(i * n + j);
        std::cout << "\n";
    }
} catch (...) {}
}

int main()
{
    auto A_i = new_array_ptr<int, 1>({0, 1, 2, 3, 1, 0, 2, 0});
    auto A_j = new_array_ptr<int, 1>({1, 2, 3, 0, 0, 2, 1, 3});

    auto C_v = new_array_ptr<double, 1>({1., 1., 1., 1., 0.1, 0.1, 0.1, 0.1});

    int n = 4;
    tsp(n, Matrix::sparse(n, n, A_i, A_j, 1.), Matrix::sparse(n, n, A_i, A_j, C_v), true, false);
    tsp(n, Matrix::sparse(n, n, A_i, A_j, 1.), Matrix::sparse(n, n, A_i, A_j, C_v), true, true);

    return 0;
}

```

PROBLEM FORMULATION AND SOLUTIONS

In this chapter we will discuss the following issues:

- The formal, mathematical formulations of the problem types that **MOSEK** can solve and their duals.
- The solution information produced by **MOSEK**.
- The infeasibility certificate produced by **MOSEK** if the problem is infeasible.

11.1 Linear Optimization

A linear optimization problem can be written as

$$\begin{array}{llll} \text{minimize} & & c^T x + c^f & \\ \text{subject to} & l^c \leq & Ax & \leq u^c, \\ & l^x \leq & x & \leq u^x, \end{array} \quad (11.1)$$

where

- m is the number of constraints.
- n is the number of decision variables.
- $x \in \mathbb{R}^n$ is a vector of decision variables.
- $c \in \mathbb{R}^n$ is the linear part of the objective function.
- $A \in \mathbb{R}^{m \times n}$ is the constraint matrix.
- $l^c \in \mathbb{R}^m$ is the lower limit on the activity for the constraints.
- $u^c \in \mathbb{R}^m$ is the upper limit on the activity for the constraints.
- $l^x \in \mathbb{R}^n$ is the lower limit on the activity for the variables.
- $u^x \in \mathbb{R}^n$ is the upper limit on the activity for the variables.

A primal solution (x) is *(primal) feasible* if it satisfies all constraints in (11.1). If (11.1) has at least one primal feasible solution, then (11.1) is said to be (primal) feasible.

In case (11.1) does not have a feasible solution, the problem is said to be *(primal) infeasible*.

11.1.1 Duality for Linear Optimization

Corresponding to the primal problem (11.1), there is a dual problem

$$\begin{array}{ll} \text{maximize} & (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f \\ & A^T y + s_l^x - s_u^x = c, \\ \text{subject to} & -y + s_l^c - s_u^c = 0, \\ & s_l^c, s_u^c, s_l^x, s_u^x \geq 0. \end{array} \quad (11.2)$$

If a bound in the primal problem is plus or minus infinity, the corresponding dual variable is fixed at 0, and we use the convention that the product of the bound value and the corresponding dual variable is 0. E.g.

$$l_j^x = -\infty \quad \Rightarrow \quad (s_l^x)_j = 0 \text{ and } l_j^x \cdot (s_l^x)_j = 0.$$

This is equivalent to removing variable $(s_l^x)_j$ from the dual problem. A solution

$$(y, s_l^c, s_u^c, s_l^x, s_u^x)$$

to the dual problem is feasible if it satisfies all the constraints in (11.2). If (11.2) has at least one feasible solution, then (11.2) is *(dual) feasible*, otherwise the problem is *(dual) infeasible*.

A Primal-dual Feasible Solution

A solution

$$(x, y, s_l^c, s_u^c, s_l^x, s_u^x)$$

is denoted a *primal-dual feasible solution*, if (x) is a solution to the primal problem (11.1) and $(y, s_l^c, s_u^c, s_l^x, s_u^x)$ is a solution to the corresponding dual problem (11.2).

The Duality Gap

Let

$$(x^*, y^*, (s_l^c)^*, (s_u^c)^*, (s_l^x)^*, (s_u^x)^*)$$

be a primal-dual feasible solution, and let

$$(x^c)^* := Ax^*.$$

For a primal-dual feasible solution we define the *duality gap* as the difference between the primal and the dual objective value,

$$\begin{aligned} c^T x^* + c^f - \{ & (l^c)^T (s_l^c)^* - (u^c)^T (s_u^c)^* + (l^x)^T (s_l^x)^* - (u^x)^T (s_u^x)^* + c^f \} \\ &= \sum_{i=0}^{m-1} [(s_l^c)^* ((x_i^c)^* - l_i^c) + (s_u^c)^* (u_i^c - (x_i^c)^*)] \\ &+ \sum_{j=0}^{n-1} [(s_l^x)^* (x_j - l_j^x) + (s_u^x)^* (u_j^x - x_j^*)] \geq 0 \end{aligned} \quad (11.3)$$

where the first relation can be obtained by transposing and multiplying the dual constraints (11.2) by x^* and $(x^c)^*$ respectively, and the second relation comes from the fact that each term in each sum is nonnegative. It follows that the primal objective will always be greater than or equal to the dual objective.

An Optimal Solution

It is well-known that a linear optimization problem has an optimal solution if and only if there exist feasible primal and dual solutions so that the duality gap is zero, or, equivalently, that the *complementarity conditions*

$$\begin{aligned} (s_l^c)^* ((x_i^c)^* - l_i^c) &= 0, & i = 0, \dots, m-1, \\ (s_u^c)^* (u_i^c - (x_i^c)^*) &= 0, & i = 0, \dots, m-1, \\ (s_l^x)^* (x_j^* - l_j^x) &= 0, & j = 0, \dots, n-1, \\ (s_u^x)^* (u_j^x - x_j^*) &= 0, & j = 0, \dots, n-1, \end{aligned}$$

are satisfied.

If (11.1) has an optimal solution and **MOSEK** solves the problem successfully, both the primal and dual solution are reported, including a status indicating the exact state of the solution.

11.1.2 Infeasibility for Linear Optimization

Primal Infeasible Problems

If the problem (11.1) is infeasible (has no feasible solution), **MOSEK** will report a certificate of primal infeasibility: The dual solution reported is the certificate of infeasibility, and the primal solution is undefined.

A certificate of primal infeasibility is a feasible solution to the modified dual problem

$$\begin{aligned} & \text{maximize} && (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x \\ & \text{subject to} && \\ & && A^T y + s_l^x - s_u^x = 0, \\ & && -y + s_l^c - s_u^c = 0, \\ & && s_l^c, s_u^c, s_l^x, s_u^x \geq 0, \end{aligned} \tag{11.4}$$

such that the objective value is strictly positive, i.e. a solution

$$(y^*, (s_l^c)^*, (s_u^c)^*, (s_l^x)^*, (s_u^x)^*)$$

to (11.4) so that

$$(l^c)^T (s_l^c)^* - (u^c)^T (s_u^c)^* + (l^x)^T (s_l^x)^* - (u^x)^T (s_u^x)^* > 0.$$

Such a solution implies that (11.4) is unbounded, and that its dual is infeasible. As the constraints to the dual of (11.4) are identical to the constraints of problem (11.1), we thus have that problem (11.1) is also infeasible.

Dual Infeasible Problems

If the problem (11.2) is infeasible (has no feasible solution), **MOSEK** will report a certificate of dual infeasibility: The primal solution reported is the certificate of infeasibility, and the dual solution is undefined.

A certificate of dual infeasibility is a feasible solution to the modified primal problem

$$\begin{aligned} & \text{minimize} && c^T x \\ & \text{subject to} && \hat{l}^c \leq Ax \leq \hat{u}^c, \\ & && \hat{l}^x \leq x \leq \hat{u}^x, \end{aligned} \tag{11.5}$$

where

$$\hat{l}_i^c = \begin{cases} 0 & \text{if } l_i^c > -\infty, \\ -\infty & \text{otherwise,} \end{cases} \quad \text{and} \quad \hat{u}_i^c := \begin{cases} 0 & \text{if } u_i^c < \infty, \\ \infty & \text{otherwise,} \end{cases}$$

and

$$\hat{l}_j^x = \begin{cases} 0 & \text{if } l_j^x > -\infty, \\ -\infty & \text{otherwise,} \end{cases} \quad \text{and} \quad \hat{u}_j^x := \begin{cases} 0 & \text{if } u_j^x < \infty, \\ \infty & \text{otherwise,} \end{cases}$$

such that

$$c^T x < 0.$$

Such a solution implies that (11.5) is unbounded, and that its dual is infeasible. As the constraints to the dual of (11.5) are identical to the constraints of problem (11.2), we thus have that problem (11.2) is also infeasible.

Primal and Dual Infeasible Case

In case that both the primal problem (11.1) and the dual problem (11.2) are infeasible, **MOSEK** will report only one of the two possible certificates — which one is not defined (**MOSEK** returns the first certificate found).

Minimalization vs. Maximalization

When the objective sense of problem (11.1) is maximization, i.e.

$$\begin{array}{llll} \text{maximize} & & c^T x + c^f \\ \text{subject to} & l^c \leq & Ax & \leq u^c, \\ & l^x \leq & x & \leq u^x, \end{array}$$

the objective sense of the dual problem changes to minimization, and the domain of all dual variables changes sign in comparison to (11.2). The dual problem thus takes the form

$$\begin{array}{ll} \text{minimize} & (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f \\ \text{subject to} & \\ & A^T y + s_l^x - s_u^x = c, \\ & -y + s_l^c - s_u^c = 0, \\ & s_l^c, s_u^c, s_l^x, s_u^x \leq 0. \end{array}$$

This means that the duality gap, defined in (11.3) as the primal minus the dual objective value, becomes nonpositive. It follows that the dual objective will always be greater than or equal to the primal objective. The primal infeasibility certificate will be reported by **MOSEK** as a solution to the system

$$\begin{array}{l} A^T y + s_l^x - s_u^x = 0, \\ -y + s_l^c - s_u^c = 0, \\ s_l^c, s_u^c, s_l^x, s_u^x \leq 0, \end{array} \quad (11.6)$$

such that the objective value is strictly negative

$$(l^c)^T (s_l^c)^* - (u^c)^T (s_u^c)^* + (l^x)^T (s_l^x)^* - (u^x)^T (s_u^x)^* < 0.$$

Similarly, the certificate of dual infeasibility is an x satisfying the requirements of (11.5) such that $c^T x > 0$.

11.2 Conic Quadratic Optimization

Conic quadratic optimization is an extension of linear optimization (see Sec. 11.1) allowing conic domains to be specified for subsets of the problem variables. A conic quadratic optimization problem can be written as

$$\begin{array}{llll} \text{minimize} & & c^T x + c^f \\ \text{subject to} & l^c \leq & Ax & \leq u^c, \\ & l^x \leq & x & \leq u^x, \\ & & x \in \mathcal{K}, \end{array} \quad (11.7)$$

where set \mathcal{K} is a Cartesian product of convex cones, namely $\mathcal{K} = \mathcal{K}_1 \times \cdots \times \mathcal{K}_p$. Having the domain restriction, $x \in \mathcal{K}$, is thus equivalent to

$$x^t \in \mathcal{K}_t \subseteq \mathbb{R}^{n_t},$$

where $x = (x^1, \dots, x^p)$ is a partition of the problem variables. Please note that the n -dimensional Euclidean space \mathbb{R}^n is a cone itself, so simple linear variables are still allowed.

MOSEK supports only a limited number of cones, specifically:

- The \mathbb{R}^n set.
- The quadratic cone:

$$\mathcal{Q}^n = \left\{ x \in \mathbb{R}^n : x_1 \geq \sqrt{\sum_{j=2}^n x_j^2} \right\}.$$

- The rotated quadratic cone:

$$\mathcal{Q}_r^n = \left\{ x \in \mathbb{R}^n : 2x_1x_2 \geq \sum_{j=3}^n x_j^2, \quad x_1 \geq 0, \quad x_2 \geq 0 \right\}.$$

Although these cones may seem to provide only limited expressive power they can be used to model a wide range of problems as demonstrated in [\[MOSEKApS12\]](#).

11.2.1 Duality for Conic Quadratic Optimization

The dual problem corresponding to the conic quadratic optimization problem (11.7) is given by

$$\begin{aligned} & \text{maximize} && (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f \\ & \text{subject to} && \\ & && A^T y + s_l^x - s_u^x + s_n^x = c \\ & && -y + s_l^c - s_u^c = 0, \\ & && s_l^c, s_u^c, s_l^x, s_u^x \geq 0, \\ & && s_n^x \in \mathcal{K}^*, \end{aligned} \tag{11.8}$$

where the dual cone \mathcal{K}^* is a Cartesian product of the cones

$$\mathcal{K}^* = \mathcal{K}_1^* \times \cdots \times \mathcal{K}_p^*,$$

where each \mathcal{K}_t^* is the dual cone of \mathcal{K}_t . For the cone types **MOSEK** can handle, the relation between the primal and dual cone is given as follows:

- The \mathbb{R}^n set:

$$\mathcal{K}_t = \mathbb{R}^{n_t} \quad \Leftrightarrow \quad \mathcal{K}_t^* = \{s \in \mathbb{R}^{n_t} : s = 0\}.$$

- The quadratic cone:

$$\mathcal{K}_t = \mathcal{Q}^{n_t} \quad \Leftrightarrow \quad \mathcal{K}_t^* = \mathcal{Q}^{n_t} = \left\{ s \in \mathbb{R}^{n_t} : s_1 \geq \sqrt{\sum_{j=2}^{n_t} s_j^2} \right\}.$$

- The rotated quadratic cone:

$$\mathcal{K}_t = \mathcal{Q}_r^{n_t} \quad \Leftrightarrow \quad \mathcal{K}_t^* = \mathcal{Q}_r^{n_t} = \left\{ s \in \mathbb{R}^{n_t} : 2s_1s_2 \geq \sum_{j=3}^{n_t} s_j^2, \quad s_1 \geq 0, \quad s_2 \geq 0 \right\}.$$

Please note that the dual problem of the dual problem is identical to the original primal problem.

11.2.2 Infeasibility for Conic Quadratic Optimization

In case **MOSEK** finds a problem to be infeasible it reports a certificate of infeasibility. This works exactly as for linear problems (see [Sec. 11.1.2](#)).

Primal Infeasible Problems

If the problem (11.7) is infeasible, **MOSEK** will report a certificate of primal infeasibility: The dual solution reported is the certificate of infeasibility, and the primal solution is undefined.

A certificate of primal infeasibility is a feasible solution to the problem

$$\begin{aligned} & \text{maximize} && (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x \\ & \text{subject to} && \\ & && A^T y + s_l^x - s_u^x + s_n^x = 0, \\ & && -y + s_l^c - s_u^c = 0, \\ & && s_l^c, s_u^c, s_l^x, s_u^x \geq 0, \\ & && s_n^x \in \mathcal{K}^*, \end{aligned}$$

such that the objective value is strictly positive.

Dual infeasible problems

If the problem (11.8) is infeasible, **MOSEK** will report a certificate of dual infeasibility: The primal solution reported is the certificate of infeasibility, and the dual solution is undefined.

A certificate of dual infeasibility is a feasible solution to the problem

$$\begin{aligned} & \text{minimize} && c^T x \\ & \text{subject to} && \hat{l}^c \leq Ax \leq \hat{u}^c, \\ & && \hat{l}^x \leq x \leq \hat{u}^x, \\ & && x \in \mathcal{K}, \end{aligned}$$

where

$$\hat{l}_i^c = \begin{cases} 0 & \text{if } l_i^c > -\infty, \\ -\infty & \text{otherwise,} \end{cases} \quad \text{and} \quad \hat{u}_i^c := \begin{cases} 0 & \text{if } u_i^c < \infty, \\ \infty & \text{otherwise,} \end{cases}$$

and

$$\hat{l}_j^x = \begin{cases} 0 & \text{if } l_j^x > -\infty, \\ -\infty & \text{otherwise,} \end{cases} \quad \text{and} \quad \hat{u}_j^x := \begin{cases} 0 & \text{if } u_j^x < \infty, \\ \infty & \text{otherwise,} \end{cases}$$

such that the objective value is strictly negative.

11.3 Semidefinite Optimization

Semidefinite optimization is an extension of conic quadratic optimization (see Sec. 11.2) allowing positive semidefinite matrix variables to be used in addition to the usual scalar variables. A semidefinite optimization problem can be written as

$$\begin{aligned} & \text{minimize} && \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle \bar{C}_j, \bar{X}_j \rangle + c^f \\ & \text{subject to} && \begin{aligned} l_i^c &\leq && \sum_{j=0}^{n-1} a_{ij} x_j + \sum_{j=0}^{p-1} \langle \bar{A}_{ij}, \bar{X}_j \rangle &\leq & u_i^c, & i = 0, \dots, m-1 \\ l_j^x &\leq && x_j &\leq & u_j^x, & j = 0, \dots, n-1 \\ &&& x \in \mathcal{K}, \bar{X}_j \in \mathcal{S}_+^{r_j}, && j = 0, \dots, p-1 \end{aligned} \end{aligned} \quad (11.9)$$

where the problem has p symmetric positive semidefinite variables $\bar{X}_j \in \mathcal{S}_+^{r_j}$ of dimension r_j with symmetric coefficient matrices $\bar{C}_j \in \mathcal{S}^{r_j}$ and $\bar{A}_{ij} \in \mathcal{S}^{r_j}$. We use standard notation for the matrix inner product, i.e., for $U, V \in \mathbb{R}^{m \times n}$ we have

$$\langle U, V \rangle := \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} U_{ij} V_{ij}.$$

With semidefinite optimization we can model a wide range of problems as demonstrated in [MOSEKApS12].

11.3.1 Duality for Semidefinite Optimization

The dual problem corresponding to the semidefinite optimization problem (11.9) is given by

$$\begin{aligned} & \text{maximize} && (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x + c^f \\ & \text{subject to} && \begin{aligned} c - A^T y + s_u^x - s_l^x &= s_n^x, \\ \bar{C}_j - \sum_{i=0}^m y_i \bar{A}_{ij} &= \bar{S}_j, && j = 0, \dots, p-1 \\ s_l^c - s_u^c &= y, \\ s_l^c, s_u^c, s_l^x, s_u^x &\geq 0, \\ s_n^x &\in \mathcal{K}^*, \quad \bar{S}_j \in \mathcal{S}_+^{r_j}, && j = 0, \dots, p-1 \end{aligned} \end{aligned} \quad (11.10)$$

where $A \in \mathbb{R}^{m \times n}$, $A_{ij} = a_{ij}$, which is similar to the dual problem for conic quadratic optimization (see Sec. 11.2.1), except for the addition of dual constraints

$$\left(\bar{C}_j - \sum_{i=0}^m y_i \bar{A}_{ij} \right) \in \mathcal{S}_+^{r_j}.$$

Note that the dual of the dual problem is identical to the original primal problem.

11.3.2 Infeasibility for Semidefinite Optimization

In case **MOSEK** finds a problem to be infeasible it reports a certificate of the infeasibility. This works exactly as for linear problems (see Sec. 11.1.2).

Primal Infeasible Problems

If the problem (11.9) is infeasible, **MOSEK** will report a certificate of primal infeasibility: The dual solution reported is a certificate of infeasibility, and the primal solution is undefined.

A certificate of primal infeasibility is a feasible solution to the problem

$$\begin{aligned} & \text{maximize} && (l^c)^T s_l^c - (u^c)^T s_u^c + (l^x)^T s_l^x - (u^x)^T s_u^x \\ & \text{subject to} && A^T y + s_l^x - s_u^x + s_n^x = 0, \\ & && \sum_{i=0}^{m-1} y_i \bar{A}_{ij} + \bar{S}_j = 0, && j = 0, \dots, p-1 \\ & && -y + s_l^c - s_u^c = 0, \\ & && s_l^c, s_u^c, s_l^x, s_u^x \geq 0, \\ & && s_n^x \in \mathcal{K}^*, \quad \bar{S}_j \in \mathcal{S}_+^{r_j}, && j = 0, \dots, p-1 \end{aligned}$$

such that the objective value is strictly positive.

Dual Infeasible Problems

If the problem (11.10) is infeasible, **MOSEK** will report a certificate of dual infeasibility: The primal solution reported is the certificate of infeasibility, and the dual solution is undefined.

A certificate of dual infeasibility is a feasible solution to the problem

$$\begin{aligned} & \text{minimize} && \sum_{j=0}^{n-1} c_j x_j + \sum_{j=0}^{p-1} \langle \bar{C}_j, \bar{X}_j \rangle \\ & \text{subject to} && \hat{l}_i^c \leq \sum_{j=1}^n a_{ij} x_j + \sum_{j=0}^{p-1} \langle \bar{A}_{ij}, \bar{X}_j \rangle \leq \hat{u}_i^c, \quad i = 0, \dots, m-1 \\ & && \hat{l}^x \leq \begin{matrix} x \\ \bar{X}_j \end{matrix} \leq \hat{u}^x, \\ & && x \in \mathcal{K}, \quad \bar{X}_j \in \mathcal{S}_+^{r_j}, && j = 0, \dots, p-1 \end{aligned}$$

where

$$\hat{l}_i^c = \begin{cases} 0 & \text{if } l_i^c > -\infty, \\ -\infty & \text{otherwise,} \end{cases} \quad \text{and} \quad \hat{u}_i^c := \begin{cases} 0 & \text{if } u_i^c < \infty, \\ \infty & \text{otherwise,} \end{cases}$$

and

$$\hat{l}_j^x = \begin{cases} 0 & \text{if } l_j^x > -\infty, \\ -\infty & \text{otherwise,} \end{cases} \quad \text{and} \quad \hat{u}_j^x := \begin{cases} 0 & \text{if } u_j^x < \infty, \\ \infty & \text{otherwise,} \end{cases}$$

such that the objective value is strictly negative.

THE OPTIMIZERS FOR CONTINUOUS PROBLEMS

The most essential part of **MOSEK** are the optimizers. This chapter describes the optimizers for the class of *continuous problems* without integer variables, that is:

- linear problems,
- conic problems (quadratic and semidefinite).

MOSEK offers an interior-point optimizer for each class of problems and also a simplex optimizer for linear problems. The structure of a successful optimization process is roughly:

- **Presolve**
 1. *Elimination*: Reduce the size of the problem.
 2. *Dualizer*: Choose whether to solve the primal or the dual form of the problem.
 3. *Scaling*: Scale the problem for better numerical stability.
- **Optimization**
 1. *Optimize*: Solve the problem using selected method.
 2. *Terminate*: Stop the optimization when specific termination criteria have been met.
 3. *Report*: Return the solution or an infeasibility certificate.

The preprocessing stage is transparent to the user, but useful to know about for tuning purposes. The purpose of the preprocessing steps is to make the actual optimization more efficient and robust. We discuss the details of the above steps in the following sections.

12.1 Presolve

Before an optimizer actually performs the optimization the problem is preprocessed using the so-called presolve. The purpose of the presolve is to

1. remove redundant constraints,
2. eliminate fixed variables,
3. remove linear dependencies,
4. substitute out (implied) free variables, and
5. reduce the size of the optimization problem in general.

After the presolved problem has been optimized the solution is automatically postsolved so that the returned solution is valid for the original problem. Hence, the presolve is completely transparent. For further details about the presolve phase, please see [\[AA95\]](#) and [\[AGMX96\]](#).

It is possible to fine-tune the behavior of the presolve or to turn it off entirely. If presolve consumes too much time or memory compared to the reduction in problem size gained it may be disabled. This is done by setting the parameter `presolveUse` to `"off"`. The two most time-consuming steps of the presolve are

- the eliminator, and
- the linear dependency check.

Therefore, in some cases it is worthwhile to disable one or both of these.

Numerical issues in the presolve

During the presolve the problem is reformulated so that it hopefully solves faster. However, in rare cases the presolved problem may be harder to solve than the original problem. The presolve may also be infeasible although the original problem is not. If it is suspected that the presolved problem is much harder to solve than the original, we suggest to first turn the eliminator off by setting the parameter `presolveEliminatorMaxNumTries` to 0. If that does not help, then trying to turn entire presolve off may help.

Since all computations are done in finite precision, the presolve employs some tolerances when concluding a variable is fixed or a constraint is redundant. If it happens that **MOSEK** incorrectly concludes a problem is primal or dual infeasible, then it is worthwhile to try to reduce the parameters `presolveTolX` and `presolveTolS`. However, if reducing the parameters actually helps then this should be taken as an indication that the problem is badly formulated.

Eliminator

The purpose of the eliminator is to eliminate free and implied free variables from the problem using substitution. For instance, given the constraints

$$\begin{aligned} y &= \sum_j x_j, \\ y, x &\geq 0, \end{aligned}$$

y is an implied free variable that can be substituted out of the problem, if deemed worthwhile. If the eliminator consumes too much time or memory compared to the reduction in problem size gained it may be disabled. This can be done by setting the parameter `presolveEliminatorMaxNumTries` to 0. In rare cases the eliminator may cause that the problem becomes much hard to solve.

Linear dependency checker

The purpose of the linear dependency check is to remove linear dependencies among the linear equalities. For instance, the three linear equalities

$$\begin{aligned} x_1 + x_2 + x_3 &= 1, \\ x_1 + 0.5x_2 &= 0.5, \\ 0.5x_2 + x_3 &= 0.5. \end{aligned}$$

contain exactly one linear dependency. This implies that one of the constraints can be dropped without changing the set of feasible solutions. Removing linear dependencies is in general a good idea since it reduces the size of the problem. Moreover, the linear dependencies are likely to introduce numerical problems in the optimization phase. It is best practice to build models without linear dependencies, but that is not always easy for the user to control. If the linear dependencies are removed at the modelling stage, the linear dependency check can safely be disabled by setting the parameter `presolveLindepUse` to `"off"`.

Dualizer

All linear, conic, and convex optimization problems have an equivalent dual problem associated with them. **MOSEK** has built-in heuristics to determine if it is more efficient to solve the primal or dual problem. The form (primal or dual) is displayed in the **MOSEK** log and available as an information item from the solver. Should the internal heuristics not choose the most efficient form of the problem it may be worthwhile to set the dualizer manually by setting the parameters:

- `intpntSolveForm`: In case of the interior-point optimizer.
- `simSolveForm`: In case of the simplex optimizer.

Note that currently only linear and conic quadratic problems may be automatically dualized.

Scaling

Problems containing data with large and/or small coefficients, say $1.0e + 9$ or $1.0e - 7$, are often hard to solve. Significant digits may be truncated in calculations with finite precision, which can result in the optimizer relying on inaccurate data. Since computers work in finite precision, extreme coefficients should be avoided. In general, data around the same *order of magnitude* is preferred, and we will refer to a problem, satisfying this loose property, as being *well-scaled*. If the problem is not well scaled, **MOSEK** will try to scale (multiply) constraints and variables by suitable constants. **MOSEK** solves the scaled problem to improve the numerical properties.

The scaling process is transparent, i.e. the solution to the original problem is reported. It is important to be aware that the optimizer terminates when the termination criterion is met on the scaled problem, therefore significant primal or dual infeasibilities may occur after unscaling for badly scaled problems. The best solution of this issue is to reformulate the problem, making it better scaled.

By default **MOSEK** heuristically chooses a suitable scaling. The scaling for interior-point and simplex optimizers can be controlled with the parameters `intpntScaling` and `simScaling` respectively.

12.2 Using Multiple Threads in an Optimizer

Multithreading in interior-point optimizers

The interior-point optimizers in **MOSEK** have been parallelized. This means that if you solve linear, quadratic, conic, or general convex optimization problem using the interior-point optimizer, you can take advantage of multiple CPU's. By default **MOSEK** will automatically select the number of threads to be employed when solving the problem. However, the maximum number of threads employed can be changed by setting the parameter `numThreads`. This should never exceed the number of cores on the computer.

The speed-up obtained when using multiple threads is highly problem and hardware dependent, and consequently, it is advisable to compare single threaded and multi threaded performance for the given problem type to determine the optimal settings. For small problems, using multiple threads is not be worthwhile and may even be counter productive because of the additional coordination overhead. Therefore, it may be advantageous to disable multithreading using the parameter `intpntMultiThread`.

The interior-point optimizer parallelizes big tasks such linear algebra computations.

Thread Safety

The **MOSEK** API is thread-safe provided that a task is only modified or accessed from one thread at any given time. Also accessing two or more separate tasks from threads at the same time is safe. Sharing an environment between threads is safe.

Determinism

The optimizers are run-to-run deterministic which means if a problem is solved twice on the same computer using the same parameter setting and exactly the same input then exactly the same results is obtained. One restriction is that no time limits must be imposed because the time taken to perform an operation on a computer is dependent on many factors such as the current workload.

12.3 Linear Optimization

12.3.1 Optimizer Selection

Two different types of optimizers are available for linear problems: The default is an interior-point method, and the alternative is the simplex method (primal or dual). The optimizer can be selected using the parameter *optimizer*.

The Interior-point or the Simplex Optimizer?

Given a linear optimization problem, which optimizer is the best: the simplex or the interior-point optimizer? It is impossible to provide a general answer to this question. However, the interior-point optimizer behaves more predictably: it tends to use between 20 and 100 iterations, almost independently of problem size, but cannot perform warm-start. On the other hand the simplex method can take advantage of an initial solution, but is less predictable from cold-start. The interior-point optimizer is used by default.

The Primal or the Dual Simplex Variant?

MOSEK provides both a primal and a dual simplex optimizer. Predicting which simplex optimizer is faster is impossible, however, in recent years the dual optimizer has seen several algorithmic and computational improvements, which, in our experience, make it faster on average than the primal version. Still, it depends much on the problem structure and size. Setting the *optimizer* parameter to *"freeSimplex"* instructs **MOSEK** to choose one of the simplex variants automatically.

To summarize, if you want to know which optimizer is faster for a given problem type, it is best to try all the options.

12.3.2 The Interior-point Optimizer

The purpose of this section is to provide information about the algorithm employed in the **MOSEK** interior-point optimizer for linear problems and about its termination criteria.

The homogeneous primal-dual problem

In order to keep the discussion simple it is assumed that **MOSEK** solves linear optimization problems of standard form

$$\begin{aligned} &\text{minimize} && c^T x \\ &\text{subject to} && Ax = b, \\ &&& x \geq 0. \end{aligned} \tag{12.1}$$

This is in fact what happens inside **MOSEK**; for efficiency reasons **MOSEK** converts the problem to standard form before solving, then converts it back to the input form when reporting the solution.

Since it is not known beforehand whether problem (12.1) has an optimal solution, is primal infeasible or is dual infeasible, the optimization algorithm must deal with all three situations. This is the reason why **MOSEK** solves the so-called homogeneous model

$$\begin{aligned} Ax - b\tau &= 0, \\ A^T y + s - c\tau &= 0, \\ -c^T x + b^T y - \kappa &= 0, \\ x, s, \tau, \kappa &\geq 0, \end{aligned} \tag{12.2}$$

where y and s correspond to the dual variables in (12.1), and τ and κ are two additional scalar variables. Note that the homogeneous model (12.2) always has solution since

$$(x, y, s, \tau, \kappa) = (0, 0, 0, 0, 0)$$

is a solution, although not a very interesting one. Any solution

$$(x^*, y^*, s^*, \tau^*, \kappa^*)$$

to the homogeneous model (12.2) satisfies

$$x_j^* s_j^* = 0 \text{ and } \tau^* \kappa^* = 0.$$

Moreover, there is always a solution that has the property $\tau^* + \kappa^* > 0$.

First, assume that $\tau^* > 0$. It follows that

$$\begin{aligned} A \frac{x^*}{\tau^*} &= b, \\ A^T \frac{y^*}{\tau^*} + \frac{s^*}{\tau^*} &= c, \\ -c^T \frac{x^*}{\tau^*} + b^T \frac{y^*}{\tau^*} &= 0, \\ x^*, s^*, \tau^*, \kappa^* &\geq 0. \end{aligned}$$

This shows that $\frac{x^*}{\tau^*}$ is a primal optimal solution and $(\frac{y^*}{\tau^*}, \frac{s^*}{\tau^*})$ is a dual optimal solution; this is reported as the optimal interior-point solution since

$$(x, y, s) = \left\{ \frac{x^*}{\tau^*}, \frac{y^*}{\tau^*}, \frac{s^*}{\tau^*} \right\}$$

is a primal-dual optimal solution (see Sec. 11.1 for the mathematical background on duality and optimality).

On other hand, if $\kappa^* > 0$ then

$$\begin{aligned} Ax^* &= 0, \\ A^T y^* + s^* &= 0, \\ -c^T x^* + b^T y^* &= \kappa^*, \\ x^*, s^*, \tau^*, \kappa^* &\geq 0. \end{aligned}$$

This implies that at least one of

$$c^T x^* < 0 \tag{12.3}$$

or

$$b^T y^* > 0 \tag{12.4}$$

is satisfied. If (12.3) is satisfied then x^* is a certificate of dual infeasibility, whereas if (12.4) is satisfied then y^* is a certificate of primal infeasibility.

In summary, by computing an appropriate solution to the homogeneous model, all information required for a solution to the original problem is obtained. A solution to the homogeneous model can be computed using a primal-dual interior-point algorithm [And09].

Interior-point Termination Criterion

For efficiency reasons it is not practical to solve the homogeneous model exactly. Hence, an exact optimal solution or an exact infeasibility certificate cannot be computed and a reasonable termination criterion has to be employed.

In the k -th iteration of the interior-point algorithm a trial solution

$$(x^k, y^k, s^k, \tau^k, \kappa^k)$$

to homogeneous model is generated, where

$$x^k, s^k, \tau^k, \kappa^k > 0.$$

Optimal case

Whenever the trial solution satisfies the criterion

$$\begin{aligned}
\left\| A \frac{x^k}{\tau^k} - b \right\|_{\infty} &\leq \epsilon_p (1 + \|b\|_{\infty}), \\
\left\| A^T \frac{y^k}{\tau^k} + \frac{s^k}{\tau^k} - c \right\|_{\infty} &\leq \epsilon_d (1 + \|c\|_{\infty}), \text{ and} \\
\min \left(\frac{(x^k)^T s^k}{(\tau^k)^2}, \left| \frac{c^T x^k}{\tau^k} - \frac{b^T y^k}{\tau^k} \right| \right) &\leq \epsilon_g \max \left(1, \frac{\min(|c^T x^k|, |b^T y^k|)}{\tau^k} \right),
\end{aligned} \tag{12.5}$$

the interior-point optimizer is terminated and

$$\frac{(x^k, y^k, s^k)}{\tau^k}$$

is reported as the primal-dual optimal solution. The interpretation of (12.5) is that the optimizer is terminated if

- $\frac{x^k}{\tau^k}$ is approximately primal feasible,
- $\left\{ \frac{y^k}{\tau^k}, \frac{s^k}{\tau^k} \right\}$ is approximately dual feasible, and
- the duality gap is almost zero.

Dual infeasibility certificate

On the other hand, if the trial solution satisfies

$$-\epsilon_i c^T x^k > \frac{\|c\|_{\infty}}{\max(1, \|b\|_{\infty})} \|Ax^k\|_{\infty}$$

then the problem is declared dual infeasible and x^k is reported as a certificate of dual infeasibility. The motivation for this stopping criterion is as follows: First assume that $\|Ax^k\|_{\infty} = 0$; then x^k is an exact certificate of dual infeasibility. Next assume that this is not the case, i.e.

$$\|Ax^k\|_{\infty} > 0,$$

and define

$$\bar{x} := \epsilon_i \frac{\max(1, \|b\|_{\infty})}{\|Ax^k\|_{\infty} \|c\|_{\infty}} x^k.$$

It is easy to verify that

$$\|A\bar{x}\|_{\infty} = \epsilon_i \frac{\max(1, \|b\|_{\infty})}{\|c\|_{\infty}} \text{ and } -c^T \bar{x} > 1,$$

which shows \bar{x} is an approximate certificate of dual infeasibility, where ϵ_i controls the quality of the approximation. A smaller value means a better approximation.

Primal infeasibility certificate

Finally, if

$$\epsilon_i b^T y^k > \frac{\|b\|_{\infty}}{\max(1, \|c\|_{\infty})} \|A^T y^k + s^k\|_{\infty}$$

then y^k is reported as a certificate of primal infeasibility.

Adjusting optimality criteria and near optimality

It is possible to adjust the tolerances ε_p , ε_d , ε_g and ε_i using parameters; see table for details.

Table 12.1: Parameters employed in termination criterion

ToleranceParameter	name
ε_p	<i>intpntTolPfeas</i>
ε_d	<i>intpntTolDfeas</i>
ε_g	<i>intpntTolRelGap</i>
ε_i	<i>intpntTolInfeas</i>

The default values of the termination tolerances are chosen such that for a majority of problems appearing in practice it is not possible to achieve much better accuracy. Therefore, tightening the tolerances usually is not worthwhile. However, an inspection of (12.5) reveals that the quality of the solution depends on $\|b\|_\infty$ and $\|c\|_\infty$; the smaller the norms are, the better the solution accuracy.

The interior-point method as implemented by **MOSEK** will converge toward optimality and primal and dual feasibility at the same rate [And09]. This means that if the optimizer is stopped prematurely then it is very unlikely that either the primal or dual solution is feasible. Another consequence is that in most cases all the tolerances, ε_p , ε_d , ε_g and ε_i , have to be relaxed together to achieve an effect.

In some cases the interior-point method terminates having found a solution not too far from meeting the optimality condition (12.5). A solution is defined as *near optimal* if scaling the termination tolerances ε_p , ε_d , ε_g and ε_i by the same factor $\varepsilon_n \in [1.0, +\infty]$ makes the condition (12.5) satisfied. A near optimal solution is therefore of lower quality but still potentially valuable. If for instance the solver stalls, i.e. it can make no more significant progress towards the optimal solution, a near optimal solution could be available and be good enough for the user. Near infeasibility certificates are defined similarly. The value of ε_n can be adjusted with the parameter *intpntCoTolNearRel*.

The basis identification discussed in Sec. 12.3.2 requires an optimal solution to work well; hence basis identification should be turned off if the termination criterion is relaxed.

To conclude the discussion in this section, relaxing the termination criterion is usually not worthwhile.

Basis Identification

An interior-point optimizer does not return an optimal basic solution unless the problem has a unique primal and dual optimal solution. Therefore, the interior-point optimizer has an optional post-processing step that computes an optimal basic solution starting from the optimal interior-point solution. More information about the basis identification procedure may be found in [AY96]. In the following we provide an overall idea of the procedure.

There are some cases in which a basic solution could be more valuable:

- a basic solution is often more accurate than an interior-point solution,
- a basic solution can be used to warm-start the simplex algorithm in case of reoptimization,
- a basic solution is in general more sparse, i.e. more variables are fixed to zero. This is particularly appealing when solving continuous relaxations of mixed integer problems, as well as in all applications in which sparser solutions are preferred.

To illustrate how the basis identification routine works, we use the following trivial example:

$$\begin{aligned} &\text{minimize} && x + y \\ &\text{subject to} && x + y = 1, \\ &&& x, y \geq 0. \end{aligned}$$

It is easy to see that all feasible solutions are also optimal. In particular, there are two basic solutions, namely

$$\begin{aligned} (x_1^*, y_1^*) &= (1, 0), \\ (x_2^*, y_2^*) &= (0, 1). \end{aligned}$$

- **PRSTATUS**: This number converges to 1 if the problem has an optimal solution whereas it converges to -1 if that is not the case.
- **POBJ**: $c^T x^k / \tau^k$. An estimate for the primal objective value.
- **DOBJ**: $b^T y^k / \tau^k$. An estimate for the dual objective value.
- **MU**: $\frac{(x^k)^T s^k + \tau^k \kappa^k}{n+1}$. The numbers in this column should always converge to zero.
- **TIME**: Time spent since the optimization started.

12.3.3 The Simplex Optimizer

An alternative to the interior-point optimizer is the simplex optimizer. The simplex optimizer uses a different method that allows exploiting an initial guess for the optimal solution to reduce the solution time. Depending on the problem it may be faster or slower to use an initial guess; see [Sec. 12.3.1](#) for a discussion. **MOSEK** provides both a primal and a dual variant of the simplex optimizer.

Simplex Termination Criterion

The simplex optimizer terminates when it finds an optimal basic solution or an infeasibility certificate. A basic solution is optimal when it is primal and dual feasible; see [Sec. 11.1](#) for a definition of the primal and dual problem. Due to the fact that computations are performed in finite precision **MOSEK** allows violations of primal and dual feasibility within certain tolerances. The user can control the allowed primal and dual tolerances with the parameters `basisTolX` and `basisTolS`.

Setting the parameter `optimizer` to `"freeSimplex"` instructs **MOSEK** to select automatically between the primal and the dual simplex optimizers. Hence, **MOSEK** tries to choose the best optimizer for the given problem and the available solution. The same parameter can also be used to force one of the variants.

Starting From an Existing Solution

When using the simplex optimizer it may be possible to reuse an existing solution and thereby reduce the solution time significantly. When a simplex optimizer starts from an existing solution it is said to perform a *warm-start*. If the user is solving a sequence of optimization problems by solving the problem, making modifications, and solving again, **MOSEK** will warm-start automatically.

By default **MOSEK** uses presolve when performing a warm-start. If the optimizer only needs very few iterations to find the optimal solution it may be better to turn off the presolve.

Numerical Difficulties in the Simplex Optimizers

Though **MOSEK** is designed to minimize numerical instability, completely avoiding it is impossible when working in finite precision. **MOSEK** treats a “numerically unexpected behavior” event inside the optimizer as a *set-back*. The user can define how many set-backs the optimizer accepts; if that number is exceeded, the optimization will be aborted. Set-backs are a way to escape long sequences where the optimizer tries to recover from an unstable situation.

Examples of set-backs are: repeated singularities when factorizing the basis matrix, repeated loss of feasibility, degeneracy problems (no progress in objective) and other events indicating numerical difficulties. If the simplex optimizer encounters a lot of set-backs the problem is usually badly scaled; in such a situation try to reformulate it into a better scaled problem. Then, if a lot of set-backs still occur, trying one or more of the following suggestions may be worthwhile:

- Raise tolerances for allowed primal or dual feasibility: increase the value of
 - `basisTolX`, and
 - `basisTolS`.

- Raise or lower pivot tolerance: Change the *simplexAbsTolPiv* parameter.
- Switch optimizer: Try another optimizer.
- Switch off crash: Set both *simPrimalCrash* and *simDualCrash* to 0.
- Experiment with other pricing strategies: Try different values for the parameters
 - *simPrimalSelection* and
 - *simDualSelection*.
- If you are using warm-starts, in rare cases switching off this feature may improve stability. This is controlled by the *simHotstart* parameter.
- Increase maximum number of set-backs allowed controlled by *simMaxNumSetbacks*.
- If the problem repeatedly becomes infeasible try switching off the special degeneracy handling. See the parameter *simDegen* for details.

The Simplex Log

Below is a typical log output from the simplex optimizer:

Optimizer	- solved problem	:	the primal			
Optimizer	- Constraints	:	667			
Optimizer	- Scalar variables	:	1424	conic	:	0
Optimizer	- hotstart	:	no			
ITER	DEGITER(%)	PFEAS	DFEAS	POBJ	DOBJ	TIME
↪	TOTTIME					
0	0.00	1.43e+05	NA	6.5584140832e+03	NA	0.00
↪	0.02					
1000	1.10	0.00e+00	NA	1.4588289726e+04	NA	0.13
↪	0.14					
2000	0.75	0.00e+00	NA	7.3705564855e+03	NA	0.21
↪	0.22					
3000	0.67	0.00e+00	NA	6.0509727712e+03	NA	0.29
↪	0.31					
4000	0.52	0.00e+00	NA	5.5771203906e+03	NA	0.38

4533	0.49	0.00e+00	NA	5.5018458883e+03	NA	0.42
↪	0.44					

The first lines summarize the problem the optimizer is solving. This is followed by the iteration log, with the following meaning:

- ITER: Number of iterations.
- DEGITER(%): Ratio of degenerate iterations.
- PFEAS: Primal feasibility measure reported by the simplex optimizer. The numbers should be 0 if the problem is primal feasible (when the primal variant is used).
- DFEAS: Dual feasibility measure reported by the simplex optimizer. The number should be 0 if the problem is dual feasible (when the dual variant is used).
- POBJ: An estimate for the primal objective value (when the primal variant is used).
- DOBJ: An estimate for the dual objective value (when the dual variant is used).
- TIME: Time spent since this instance of the simplex optimizer was invoked (in seconds).
- TOTTIME: Time spent since optimization started (in seconds).

12.4 Conic Optimization

For conic optimization problems only an interior-point type optimizer is available.

12.4.1 The Interior-point optimizer

The homogeneous primal-dual problem

The interior-point optimizer is an implementation of the so-called homogeneous and self-dual algorithm. For a detailed description of the algorithm, please see [\[ART03\]](#). In order to keep our discussion simple we will assume that **MOSEK** solves a conic optimization problem of the form:

$$\begin{aligned} & \text{minimize} && c^T x \\ & \text{subject to} && Ax = b, \\ & && x \in \mathcal{K} \end{aligned} \tag{12.6}$$

where \mathcal{K} is a convex cone. The corresponding dual problem is

$$\begin{aligned} & \text{maximize} && b^T y \\ & \text{subject to} && A^T y + s = c, \\ & && x \in \mathcal{K}^* \end{aligned} \tag{12.7}$$

where \mathcal{K}^* is the dual cone of \mathcal{K} . See [Sec. 11.2](#) for definitions.

Since it is not known beforehand whether problem (12.6) has an optimal solution, is primal infeasible or is dual infeasible, the optimization algorithm must deal with all three situations. This is the reason that **MOSEK** solves the so-called homogeneous model

$$\begin{aligned} Ax - b\tau &= 0, \\ A^T y + s - c\tau &= 0, \\ -c^T x + b^T y - \kappa &= 0, \\ x &\in \mathcal{K}, \\ s &\in \mathcal{K}^*, \\ \tau, \kappa &\geq 0, \end{aligned} \tag{12.8}$$

where y and s correspond to the dual variables in (12.6), and τ and κ are two additional scalar variables. Note that the homogeneous model (12.8) always has a solution since

$$(x, y, s, \tau, \kappa) = (0, 0, 0, 0, 0)$$

is a solution, although not a very interesting one. Any solution

$$(x^*, y^*, s^*, \tau^*, \kappa^*)$$

to the homogeneous model (12.8) satisfies

$$(x^*)^T s^* + \tau^* \kappa^* = 0$$

i.e. complementarity. Observe that $x^* \in \mathcal{K}$ and $s^* \in \mathcal{K}^*$ implies

$$(x^*)^T s^* \geq 0$$

and therefore

$$\tau^* \kappa^* = 0.$$

since $\tau^*, \kappa^* \geq 0$. Hence, at least one of τ^* and κ^* is zero.

First, assume that $\tau^* > 0$ and hence $\kappa^* = 0$. It follows that

$$\begin{aligned} A \frac{x^*}{\tau^*} &= b, \\ A^T \frac{y^*}{\tau^*} + \frac{s^*}{\tau^*} &= c, \\ -c^T \frac{x^*}{\tau^*} + b^T \frac{y^*}{\tau^*} &= 0, \\ x^*/\tau^* &\in \mathcal{K}, \\ s^*/\tau^* &\in \mathcal{K}^*. \end{aligned}$$

This shows that $\frac{x^*}{\tau^*}$ is a primal optimal solution and $(\frac{y^*}{\tau^*}, \frac{s^*}{\tau^*})$ is a dual optimal solution; this is reported as the optimal interior-point solution since

$$(x, y, s) = \left(\frac{x^*}{\tau^*}, \frac{y^*}{\tau^*}, \frac{s^*}{\tau^*} \right)$$

is a primal-dual optimal solution.

On other hand, if $\kappa^* > 0$ then

$$\begin{aligned} Ax^* &= 0, \\ A^T y^* + s^* &= 0, \\ -c^T x^* + b^T y^* &= \kappa^*, \\ x^* &\in \mathcal{K}, \\ s^* &\in \mathcal{K}^*. \end{aligned}$$

This implies that at least one of

$$c^T x^* < 0 \tag{12.9}$$

or

$$b^T y^* > 0 \tag{12.10}$$

holds. If (12.9) is satisfied, then x^* is a certificate of dual infeasibility, whereas if (12.10) holds then y^* is a certificate of primal infeasibility.

In summary, by computing an appropriate solution to the homogeneous model, all information required for a solution to the original problem is obtained. A solution to the homogeneous model can be computed using a primal-dual interior-point algorithm [And09].

Interior-point Termination Criterion

Since computations are performed in finite precision, and for efficiency reasons, it is not possible to solve the homogeneous model exactly in general. Hence, an exact optimal solution or an exact infeasibility certificate cannot be computed and a reasonable termination criterion has to be employed.

In every iteration k of the interior-point algorithm a trial solution

$$(x^k, y^k, s^k, \tau^k, \kappa^k)$$

to the homogeneous model is generated, where

$$x^k \in \mathcal{K}, s^k \in \mathcal{K}^*, \tau^k, \kappa^k > 0.$$

Therefore, it is possible to compute the values:

$$\begin{aligned} \rho_p^k &= \arg \min_{\rho} \left\{ \rho \mid \left\| A \frac{x^k}{\tau^k} - b \right\|_{\infty} \leq \rho \varepsilon_p (1 + \|b\|_{\infty}) \right\}, \\ \rho_d^k &= \arg \min_{\rho} \left\{ \rho \mid \left\| A^T \frac{y^k}{\tau^k} + \frac{s^k}{\tau^k} - c \right\|_{\infty} \leq \rho \varepsilon_d (1 + \|c\|_{\infty}) \right\}, \\ \rho_g^k &= \arg \min_{\rho} \left\{ \rho \mid \left(\frac{(x^k)^T s^k}{(\tau^k)^2}, \left| \frac{c^T x^k}{\tau^k} - \frac{b^T y^k}{\tau^k} \right| \right) \leq \rho \varepsilon_g \max \left(1, \frac{\min(|c^T x^k|, |b^T y^k|)}{\tau^k} \right) \right\}, \\ \rho_{pi}^k &= \arg \min_{\rho} \left\{ \rho \mid \left\| A^T y^k + s^k \right\|_{\infty} \leq \rho \varepsilon_i b^T y^k, b^T y^k > 0 \right\} \text{ and} \\ \rho_{di}^k &= \arg \min_{\rho} \left\{ \rho \mid \left\| Ax^k \right\|_{\infty} \leq -\rho \varepsilon_i c^T x^k, c^T x^k < 0 \right\}. \end{aligned}$$

Note $\varepsilon_p, \varepsilon_d, \varepsilon_g$ and ε_i are nonnegative user specified tolerances.

Optimal Case

Observe ρ_p^k measures how far x^k/τ^k is from being a good approximate primal feasible solution. Indeed if $\rho_p^k \leq 1$, then

$$\left\| A \frac{x^k}{\tau^k} - b \right\|_{\infty} \leq \varepsilon_p (1 + \|b\|_{\infty}). \quad (12.11)$$

This shows the violations in the primal equality constraints for the solution x^k/τ^k is small compared to the size of b given ε_p is small.

Similarly, if $\rho_d^k \leq 1$, then $(y^k, s^k)/\tau^k$ is an approximate dual feasible solution. If in addition $\rho_g \leq 1$, then the solution $(x^k, y^k, s^k)/\tau^k$ is approximate optimal because the associated primal and dual objective values are almost identical.

In other words if $\max(\rho_p^k, \rho_d^k, \rho_g^k) \leq 1$, then

$$\frac{(x^k, y^k, s^k)}{\tau^k}$$

is an approximate optimal solution.

Dual Infeasibility Certificate

Next assume that $\rho_{di}^k \leq 1$ and hence

$$\|Ax^k\|_{\infty} \leq -\varepsilon_i c^T x^k \text{ and } -c^T x^k > 0$$

holds. Now in this case the problem is declared dual infeasible and x^k is reported as a certificate of dual infeasibility. The motivation for this stopping criterion is as follows. Let

$$\bar{x} := \frac{x^k}{-c^T x^k}$$

and it is easy to verify that

$$\|A\bar{x}\|_{\infty} \leq \varepsilon_i \text{ and } c^T \bar{x} = -1$$

which shows \bar{x} is an approximate certificate of dual infeasibility, where ε_i controls the quality of the approximation.

Primal Infeasibility Certificate

Next assume that $\rho_{pi}^k \leq 1$ and hence

$$\|A^T y^k + s^k\|_{\infty} \leq \varepsilon_i b^T y^k \text{ and } b^T y^k > 0$$

holds. Now in this case the problem is declared primal infeasible and (y^k, s^k) is reported as a certificate of primal infeasibility. The motivation for this stopping criterion is as follows. Let

$$\bar{y} := \frac{y^k}{b^T y^k} \text{ and } \bar{s} := \frac{s^k}{b^T y^k}$$

and it is easy to verify that

$$\|A^T \bar{y} + \bar{s}\|_{\infty} \leq \varepsilon_i \text{ and } b^T \bar{y} = 1$$

which shows (y^k, s^k) is an approximate certificate of dual infeasibility, where ε_i controls the quality of the approximation.

Adjusting optimality criteria and near optimality

It is possible to adjust the tolerances ε_p , ε_d , ε_g and ε_i using parameters; see table for details.

Table 12.2: Parameters employed in termination criterion

ToleranceParameter	name
ε_p	<i>intpntCoTolPfeas</i>
ε_d	<i>intpntCoTolDfeas</i>
ε_g	<i>intpntCoTolRelGap</i>
ε_i	<i>intpntCoTolInfeas</i>

The default values of the termination tolerances are chosen such that for a majority of problems appearing in practice it is not possible to achieve much better accuracy. Therefore, tightening the tolerances usually is not worthwhile. However, an inspection of (12.11) reveals that the quality of the solution depends on $\|b\|_\infty$ and $\|c\|_\infty$; the smaller the norms are, the better the solution accuracy.

The interior-point method as implemented by **MOSEK** will converge toward optimality and primal and dual feasibility at the same rate [And09]. This means that if the optimizer is stopped prematurely then it is very unlikely that either the primal or dual solution is feasible. Another consequence is that in most cases all the tolerances, ε_p , ε_d , ε_g and ε_i , have to be relaxed together to achieve an effect.

In some cases the interior-point method terminates having found a solution not too far from meeting the optimality condition (12.11). A solution is defined as *near optimal* if scaling the termination tolerances ε_p , ε_d , ε_g and ε_i by the same factor $\varepsilon_n \in [1.0, +\infty]$ makes the condition (12.11) satisfied. A near optimal solution is therefore of lower quality but still potentially valuable. If for instance the solver stalls, i.e. it can make no more significant progress towards the optimal solution, a near optimal solution could be available and be good enough for the user. Near infeasibility certificates are defined similarly. The value of ε_n can be adjusted with the parameter *intpntCoTolNearRel*.

To conclude the discussion in this section, relaxing the termination criterion is usually not worthwhile.

The Interior-point Log

Below is a typical log output from the interior-point optimizer:

Optimizer	- threads	:	20						
Optimizer	- solved problem	:	the primal

4	1.4e-08	4.2e-09	4.9e-08	1.00e+00	7.071067941e-01	7.071067599e-01	1.4e-08	0.01	

The first line displays the number of threads used by the optimizer and the second line tells that the optimizer chose to solve the dual problem rather than the primal problem. The next line displays the problem dimensions as seen by the optimizer, and the **Factor...** lines show various statistics. This is followed by the iteration log.

Using the same notation as in Sec. 12.4.1 the columns of the iteration log have the following meaning:

- ITE: Iteration index k .

- **PFEAS**: $\|Ax^k - b\tau^k\|_\infty$. The numbers in this column should converge monotonically towards zero but may stall at low level due to rounding errors.
- **DFEAS**: $\|A^T y^k + s^k - c\tau^k\|_\infty$. The numbers in this column should converge monotonically towards zero but may stall at low level due to rounding errors.
- **GFEAS**: $|-c^T x^k + b^T y^k - \kappa^k|$. The numbers in this column should converge monotonically towards zero but may stall at low level due to rounding errors.
- **PRSTATUS**: This number converges to 1 if the problem has an optimal solution whereas it converges to -1 if that is not the case.
- **POBJ**: $c^T x^k / \tau^k$. An estimate for the primal objective value.
- **DOBJ**: $b^T y^k / \tau^k$. An estimate for the dual objective value.
- **MU**: $\frac{(x^k)^T s^k + \tau^k \kappa^k}{n+1}$. The numbers in this column should always converge to zero.
- **TIME**: Time spent since the optimization started (in seconds).

THE OPTIMIZER FOR MIXED-INTEGER PROBLEMS

A problem is a mixed-integer optimization problem when one or more of the variables are constrained to be integer valued. Readers unfamiliar with integer optimization are recommended to consult some relevant literature, e.g. the book [Wol98] by Wolsey.

13.1 The Mixed-integer Optimizer Overview

MOSEK can solve mixed-integer linear and conic quadratic problems.

By default the mixed-integer optimizer is run-to-run deterministic. This means that if a problem is solved twice on the same computer with identical parameter settings and no time limit then the obtained solutions will be identical. If a time limit is set then this may not be case since the time taken to solve a problem is not deterministic. The mixed-integer optimizer is parallelized i.e. it can exploit multiple cores during the optimization.

The solution process can be split into these phases:

1. **Presolve:** See Sec. 12.1.
2. **Cut generation:** Valid inequalities (cuts) are added to improve the lower bound.
3. **Heuristic:** Using heuristics the optimizer tries to guess a good feasible solution. Heuristics can be controlled by the parameter *mioHeuristicLevel*.
4. **Search:** The optimal solution is located by branching on integer variables.

13.2 Relaxations and bounds

It is important to understand that, in a worst-case scenario, the time required to solve integer optimization problems grows exponentially with the size of the problem (solving mixed-integer problems is NP-hard). For instance, a problem with n binary variables, may require time proportional to 2^n . The value of 2^n is huge even for moderate values of n .

In practice this implies that the focus should be on computing a near-optimal solution quickly rather than on locating an optimal solution. Even if the problem is only solved approximately, it is important to know how far the approximate solution is from an optimal one. In order to say something about the quality of an approximate solution the concept of *relaxation* is important.

Consider for example a mixed-integer optimization problem

$$\begin{aligned} z^* = \quad & \text{minimize} && c^T x \\ & \text{subject to} && Ax = b, \\ & && x \geq 0 \\ & && x_j \in \mathbb{Z}, \quad \forall j \in \mathcal{J}. \end{aligned} \tag{13.1}$$

It has the continuous relaxation

$$\begin{aligned} \underline{z} = \quad & \text{minimize} && c^T x \\ & \text{subject to} && Ax = b, \\ & && x \geq 0 \end{aligned} \tag{13.2}$$

obtained simply by ignoring the integrality restrictions. The relaxation is a continuous problem, and therefore much faster to solve to optimality with a linear (or, in the general case, conic) optimizer. We call the optimal value \underline{z} the *objective bound*. The objective bound \underline{z} normally increases during the solution search process when the continuous relaxation is gradually refined.

Moreover, if \hat{x} is any feasible solution to (13.1) and

$$\bar{z} := c^T \hat{x}$$

then

$$\underline{z} \leq z^* \leq \bar{z}.$$

These two inequalities allow us to estimate the quality of the integer solution: it is no further away from the optimum than $\bar{z} - \underline{z}$ in terms of the objective value. Whenever a mixed-integer problem is solved **MOSEK** reports this lower bound so that the quality of the reported solution can be evaluated.

13.3 Termination Criterion

In general, it is time consuming to find an exact feasible and optimal solution to an integer optimization problem, though in many practical cases it may be possible to find a sufficiently good solution. The issue of terminating the mixed-integer optimizer is rather delicate and the user has numerous possibilities of influencing it with various parameters. The mixed-integer optimizer employs a relaxed feasibility and optimality criterion to determine when a satisfactory solution is located.

A candidate solution that is feasible for the continuous relaxation is said to be an *integer feasible solution* if the criterion

$$\min(x_j - \lfloor x_j \rfloor, \lceil x_j \rceil - x_j) \leq \delta_1 \quad \forall j \in \mathcal{J}$$

is satisfied, meaning that x_j is at most δ_1 from the nearest integer.

Whenever the integer optimizer locates an integer feasible solution it will check if the criterion

$$\bar{z} - \underline{z} \leq \max(\delta_2, \delta_3 \max(10^{-10}, |\bar{z}|))$$

is satisfied. If this is the case, the integer optimizer terminates and reports the integer feasible solution as an optimal solution. If an optimal solution cannot be located after the time specified by the parameter `mioDisableTermTime` (in seconds), it may be advantageous to relax the termination criteria, and they become replaced with

$$\bar{z} - \underline{z} \leq \max(\delta_4, \delta_5 \max(10^{-10}, |\bar{z}|)).$$

Any solution satisfying those will now be reported as **near optimal** and the solver will be terminated (note that since this criterion depends on timing, the optimizer will not be run to run deterministic).

All the δ tolerances discussed above can be adjusted using suitable parameters — see Table 13.1.

Table 13.1: Tolerances for the mixed-integer optimizer.

Tolerance	Parameter name
δ_1	<code>mioTolAbsRelaxInt</code>
δ_2	<code>mioTolAbsGap</code>
δ_3	<code>mioTolRelGap</code>
δ_4	<code>mioNearTolAbsGap</code>
δ_5	<code>mioNearTolRelGap</code>

In Table 13.2 some other common parameters affecting the integer optimizer termination criterion are shown. Please note that if the effect of a parameter is delayed, the associated termination criterion is applied only after some time, specified by the *mioDisableTermTime* parameter.

Table 13.2: Other parameters affecting the integer optimizer termination criterion.

Parameter name	Delayed	Explanation
<i>mioMaxNumBranches</i>	Yes	Maximum number of branches allowed.
<i>mioMaxNumRelaxs</i>	Yes	Maximum number of relaxations allowed.
<i>mioMaxNumSolutions</i>	Yes	Maximum number of feasible integer solutions allowed.

13.4 Speeding Up the Solution Process

As mentioned previously, in many cases it is not possible to find an optimal solution to an integer optimization problem in a reasonable amount of time. Some suggestions to reduce the solution time are:

- Relax the termination criterion: In case the run time is not acceptable, the first thing to do is to relax the termination criterion — see Sec. 13.3 for details.
- Specify a good initial solution: In many cases a good feasible solution is either known or easily computed using problem-specific knowledge. If a good feasible solution is known, it is usually worthwhile to use this as a starting point for the integer optimizer.
- Improve the formulation: A mixed-integer optimization problem may be impossible to solve in one form and quite easy in another form. However, it is beyond the scope of this manual to discuss good formulations for mixed-integer problems. For discussions on this topic see for example [Wol98].

13.5 Understanding Solution Quality

To determine the quality of the solution one should check the following:

- The problem status and solution status returned by **MOSEK**, as well as constraint violations in case of suboptimal solutions.
- The *optimality gap* defined as

$$\epsilon = |(\text{objective value of feasible solution}) - (\text{objective bound})| = |\bar{z} - z|.$$

which measures how much the located solution can deviate from the optimal solution to the problem. The optimality gap can be retrieved through the information item *"mioObjAbsGap"*. Often it is more meaningful to look at the relative optimality gap normalized against the magnitude of the solution.

$$\epsilon_{\text{rel}} = \frac{|\bar{z} - z|}{\max(10^{-10}, |\bar{z}|)}.$$

The relative optimality gap is available in *"mioObjRelGap"*.

13.6 The Optimizer Log

Below is a typical log output from the mixed-integer optimizer:

Presolved problem: 6573 variables, 35728 constraints, 101258 non-zeros							
Presolved problem: 0 general integer, 4294 binary, 2279 continuous							
Clique table size: 1636							
BRANCHES	RELAXS	ACT_NDS	DEPTH	BEST_INT_OBJ	BEST_RELAX_OBJ	REL_GAP(%)	TIME

0	1	0	0	1.8331557950e+07	1.8218819866e+07	0.61	3.5
0	1	0	0	1.8300507546e+07	1.8218819866e+07	0.45	4.3
Cut generation started.							
0	2	0	0	1.8300507546e+07	1.8218819866e+07	0.45	5.3
Cut generation terminated. Time = 1.43							
0	3	0	0	1.8286893047e+07	1.8231580587e+07	0.30	7.5
15	18	1	0	1.8286893047e+07	1.8231580587e+07	0.30	10.5
31	34	1	0	1.8286893047e+07	1.8231580587e+07	0.30	11.1
51	54	1	0	1.8286893047e+07	1.8231580587e+07	0.30	11.6
91	94	1	0	1.8286893047e+07	1.8231580587e+07	0.30	12.4
171	174	1	0	1.8286893047e+07	1.8231580587e+07	0.30	14.3
331	334	1	0	1.8286893047e+07	1.8231580587e+07	0.30	17.9
[...]							
Objective of best integer solution : 1.825846762609e+07							
Best objective bound : 1.823311032986e+07							
Construct solution objective : Not employed							
Construct solution # roundings : 0							
User objective cut value : 0							
Number of cuts generated : 117							
Number of Gomory cuts : 108							
Number of CMIR cuts : 9							
Number of branches : 4425							
Number of relaxations solved : 4410							
Number of interior point iterations: 25							
Number of simplex iterations : 221131							

The first lines contain a summary of the problem as seen by the optimizer. This is followed by the iteration log. The columns have the following meaning:

- BRANCHES: Number of branches generated.
- RELAXS: Number of relaxations solved.
- ACT_NDS: Number of active branch bound nodes.
- DEPTH: Depth of the recently solved node.
- BEST_INT_OBJ: The best integer objective value, \bar{z} .
- BEST_RELAX_OBJ: The best objective bound, \underline{z} .
- REL_GAP(%): Relative optimality gap, $100\% \cdot \epsilon_{\text{rel}}$
- TIME: Time (in seconds) from the start of optimization.

Following that a summary of the optimization process is printed.

FUSION API REFERENCE

- *General API conventions.*
- **mosek::fusion** classes
 - Quick links: *Model*, *Expr*, *Variable*, *Var*, *Domain*, *Matrix*
 - *Full list*
- **Optimizer parameters:**
 - *Double*, *Integer*, *String*
 - *Full list*
 - *Browse by topic*
- **Optimizer information items:**

- *Enumerations*
- *Constants*
- *Exceptions*
- *Linear algebra utilities*

14.1 Fusion API conventions

14.1.1 General conventions

All the classes of the *Fusion* interface are contained in the namespace **mosek::fusion**. The user should not directly instantiate objects of any class other than creating a *Model*.

```
Model::t M = new Model();  
Model::t M = new Model("myModel");
```

The model is the main access point to an optimization problem and its solution. All other objects should be created through the model (*Model.variable*, *Model.constraint*, etc.) or using static factory methods (*Matrix.sparse* etc.).

The C++ *Fusion* implements its own reference counting and array types to improve garbage collection. The user will require the type definitions from two namespaces:

```
using namespace mosek::fusion;  
using namespace monty;
```

The following subsections contain the relevant API reference.

14.1.2 C++ Arrays and Pointers

Arrays

All arrays in *Fusion* are passed as objects of type `monty::ndarray` wrapped in a shared pointer:

```
std::shared_ptr<monty::ndarray<T,N>>
```

where `T` is the type of the elements and `N` is an integer denoting the number of dimensions. See `monty::ndarray` for ways to create, manipulate and iterate over arrays and `new_array_ptr` for array factory methods.

Shapes and indexes

The shape of arrays is defined by a type `monty::shape_t`, which is also used to define an N -dimensional index.

Objects and reference counting

Objects of all classes defined in the `mosek::fusion` namespace are wrapped in a reference counting pointer of type `monty::rc_ptr`. Every *Fusion* class `C` contains a definition of a type

```
typedef monty::rc_ptr<C> t;
```

for example `Model::t`, `Variable::t` etc. These pointer types should be used instead of standard pointers to ensure proper garbage collection. It is also recommended to use a finalizer if possible, as below. For example

```
Model::t M = new Model("MyModel");
auto _M = finally([&]() { M->dispose(); });
Variable::t v = M->variable(5);
```

An object will be destroyed the moment nobody refers to it any more.

14.1.3 C++ extension reference

Multidimensional arrays

`monty::ndarray<T,N>`

A template class for all arrays in *Fusion*.

Template parameters

- `T` – The type of objects stored in the array.
- `N` – The number of dimensions.

`ndarray<T,N>.ndarray<T,N>`

```
ndarray(shape_t<N> shape)
ndarray(shape_t<N> shape, T value)
ndarray(const shape_t<N> & shape, const std::function<T(ptrdiff_t)> & fLin);
ndarray(const shape_t<N> & shape, const std::function<T(const shape_t<N> &)> & fInd)
ndarray(T* vals, shape_t<N> shape)
ndarray(init_t & init)
template<typename Iterator> ndarray(const shape_t<N> & shape, Iterator begin, Iterator
↪end)
```

```
template<typename Iterable> ndarray(const shape_t<N> & shape, const typename const_
↳ iterable_t<Iterable>::t & that)
template<typename Iterable> ndarray(const shape_t<N> & shape, const const_iterable_t
↳ <Iterable> & that)
ndarray(const ndarray<T,N> & that)
ndarray(ndarray<T,N> && that)
```

Constructor of a multidimensional array object. The initializing data can have several forms:

- Default value, e.g. 0 for numerical types.
- Create a new array initialized with values generated by a generator function.

```
auto v = new ndarray<int,1>(shape(5), [](ptrdiff_t i) { return 5-i; });
auto v = new ndarray<int,2>(shape(5,5), std::function<int(const shape_t<2> &)>
↳ ([](const shape_t<2> & p) { return p[0]+p[1]; }));
```

- Initialized with values from another array.
- Initialized with an initializer list.

Arrays can also be constructed with the factory method `new_array_ptr`.

Parameters

- shape (`shape_t`) – The shape of the array.
- value (T) – The default value for all elements.
- fLin – An array-filling function taking the linear index as an argument.
- fInd – An array-filling function taking the multidimensional index as an argument.
- vals (T*) – An array with element values.
- init (init_t) – An initializer list. The type `init_t` is an N -fold nested initializer list of type `std::initializer_list`. For example, for 2-dimensional arrays this is an initializer list of initializer lists, and so forth.
- begin, end – The pointers to an iterator.
- that – Another iterable object (see `monty_base.h`) or an `ndarray` object used as initializer.

`ndarray<T,N>.operator()`

```
T& operator()(int i1, ..., int iN)
```

N -dimensional access operator. Returns the element at position (i_1, \dots, i_N) .

Example:

```
auto v = new ndarray<int,2>(shape(5,5));
(*v)(3,4) = 15;
```

Parameters `i1, ..., iN (int)` – The multi-dimensional index of the element.

`ndarray<T,N>.operator[]`

```
T& operator[](int i)
T& operator[](const shape_t<N> & idx)
```

Access operator. Returns a specific element in the array.

Parameters

- `i` (`int`) – The linear index of the element, referring to its position in the one-dimensional row-wise flattening of the array.
- `idx` (`shape_t`) – The multi-dimensional index of the element.

`ndarray<T,N>.begin`

```
T* begin()
```

An iterator pointing to the beginning of the array. Note that the iterator sees the array as a one dimensional array obtained traversing the N -dimensional array row-wise.

Example:

```
auto a = new_array_ptr<double,2>({ { 1.1, 2.2 }, { 3.3, 4.4 } } );  
for(auto x : *a) std::cout << x << " ";
```

`ndarray<T,N>.end`

```
T* end()
```

An iterator pointing to the end of the array.

`ndarray<T,N>.raw`

```
T* raw()
```

Returns a pointer to the raw data array.

`ndarray<T,N>.size`

```
size_t size()
```

Returns the number of elements in the array.

Shapes and indices

`monty::shape_t<N>`

Represents the shape of an N -dimensional array. It is in fact an N -tuple of integers. It is also used to specify an index in an N -dimensional array.

Template parameters N – The number of dimensions.

`shape_t<N>.shape_t<N>`

```
shape_t(int i1, ..., int iN)  
shape_t(int i0, shape_t<N-1> is)  
shape_t(const shape_t<N> & that)
```

Constructor of a new shape. Shapes can also be constructed with the factory method `shape`.

Parameters

- `i1, ..., iN` (`int`) – The dimensions.
- `i0` (`int`) – The first dimension.
- `is` (`shape_t`) – Shape of the remaining $N - 1$ dimensions.

- that (*shape_t*) – Another shape to be copied.

`shape_t<N>.operator[]`

```
int operator[](int i)
```

Return the size in a specific dimension.

Parameters *i* (int) – The dimension.

`shape_t<N>.tolinear`

```
int tolinear(const shape_t<N> & point)
int tolinear(int i1, ..., int iN)
```

Compute the linear index of an element within this shape. The linear index is the position of the element in the one-dimensional row-wise flattening of the shape.

Example:

```
std::cout << shape(2,3).tolinear(1,1);
4
```

Parameters

- point (*shape_t*) – The coordinates of an index within the current shape.
- *i1*, ..., *iN* (int) – The coordinates of an index within the current shape.

`shape_t<N>.begin`

```
shape_iterator<N> begin()
```

An iterator to the shape. This iterator will traverse all indices belonging to the shape in increasing linear order, i.e. in the row-wise order in the multidimensional shape, and return a object of type *shape_t* for each index.

Example:

```
for(auto p : shape(2,3)) std::cout << p;
(0,0) (0,1) (0,2) (1,0) (1,1) (1,2)
```

`shape_t<N>.end`

```
shape_iterator<N> end()
```

An iterator pointing to the end of shape.

Reference counting pointers

`monty::rc_ptr<T>`

A reference counting pointer wrapped around an object of type *T*. Implements standard pointer type operators such as `*` and `->` in the expected way. For *Fusion* classes, the reference counting pointer type `monty::rc_ptr<C>` is defined as `C::t`.

Auxiliary functions in the `monty` namespace

`new_array_ptr`

```
std::shared_ptr<ndarray<T,N>> new_array_ptr(init_t init)
```

Create a new N -dimensional array of type T and wrap it in a shared pointer.

Examples:

```
auto a1 = new_array_ptr<double,1>({ 1.1, 2.2 , 3.3, 4.4 } );  
auto a2 = new_array_ptr<double,2>({ { 1.1, 2.2 }, { 3.3, 4.4 } } );
```

Parameters `init` (`init_t`) – An initializer list. The type `init_t` is an N -fold nested initializer list of type `std::initializer_list`. For example, for 2-dimensional arrays this is an initializer list of initializer lists, and so forth.

`shape`

```
shape_t<N> shape(int i1, ..., int iN)
```

Create a new shape with the given dimensions.

Example:

```
auto s = shape(2,3,4);
```

Parameters `i1, ..., iN` (`int`) – The dimensions.

14.2 Class list

Common

- *Constraint*: Abstract base class for Constraint objects.
- *Domain*: Base class for variable and constraint domains.
- *Expr*: Represents a linear expression and provides linear operators.
- *Expression*: Abstract base class for all objects which can be used as linear expressions.
- *Matrix*: Base class for all matrix objects.
- *Model*: The object containing all data related to a single optimization model.
- *Set*: Base class shape specification objects.
- *Var*: Provides basic operations on variable objects.
- *Variable*: Abstract base class for Variable objects.

Infrequent

- *BaseSet*: Base class for 1-dimensional sets.
- *BaseVariable*: Abstract base class for Variable objects with default implementations.
- *BoundInterfaceConstraint*: Interface to either the upper bound or the lower bound of a ranged constraint.

- *BoundInterfaceVariable*: Interface to either the upper bound or the lower bound of a ranged variable.
- *CompoundConstraint*: Stacking of constraints.
- *CompoundVariable*: A stack of several other variables.
- *ConicConstraint*: Represent a conic constraint.
- *ConicVariable*: Represent a conic variable.
- *FlatExpr*: A simple sparse representation of a linear expression.
- *LinPSDDomain*: Represent a linear PSD domain.
- *LinearConstraint*: An object representing a block of linear constraints of the same type.
- *LinearDomain*: Represent a domain defined by linear constraints
- *LinearPSDConstraint*: Represents a semidefinite conic constraint.
- *LinearPSDVariable*: This class represents a positive semidefinite variable.
- *LinearVariable*: An object representing a block of linear variables of the same type.
- *ModelConstraint*: Represent a block of constraints.
- *ModelVariable*: Represent a block of variables.
- *NDSparseArray*: Representation of a sparse n-dimensional array.
- *PSDConstraint*: Represents a semidefinite conic constraint.
- *PSDDomain*: Represent the domain of PSD matrices.
- *PSDVariable*: This class represents a positive semidefinite variable.
- *PickVariable*: Represents an set of variable entries
- *QConeDomain*: A domain representing the Lorentz cone.
- *RangeDomain*: The range domain represents a ranged subset of the euclidian space.
- *RangedConstraint*: Defines a ranged constraint.
- *RangedVariable*: Defines a ranged variable.
- *RepeatVariable*: This class represents a variable repeating another variable.
- *SliceConstraint*: An alias for a subset of constraints from a single ModelConstraint.
- *SliceVariable*: An alias for a subset of variables from a single model variable.
- *SymLinearVariable*: An object representing a block of linear variables of the same type.
- *SymRangedVariable*: Defines a symmetric ranged variable.
- *SymmetricExpr*: An object representing a symmetric expression.
- *SymmetricLinearDomain*: Represent a linear domain with symmetry.
- *SymmetricRangeDomain*: Represent a ranged domain with symmetry.
- *SymmetricVariable*: An object representing a symmetric variable.

14.2.1 Class BaseSet

`mosek::fusion::BaseSet`

Base class for 1-dimensional sets.

Implements *Set*

Members *BaseSet.dim* – Return the size of the requested dimension.

Set.compare – Compare two sets.

Set.getSize – Total number of elements in the set.

Set.getname – Return a string representing the item identified by the key.

Set.idxtokey – Convert a linear index to a N-dimensional key.

Set.realnd – Number of dimensions of more than 1 element, or 1 if the number of significant dimensions is 0.

Set.slice – Create a set object representing a slice of this set.

Set.stride – Return the stride size in the given dimension.

Set.toString – Return a string representation of the set.

`BaseSet.dim`

```
int dim(int i)
```

Return the size of the requested dimension.

Parameters *i* (int) – Dimension index.

Return (int)

14.2.2 Class BaseVariable

`mosek::fusion::BaseVariable`

An abstract variable object. This class provides various default implementations of methods in *Variable*.

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

Implemented by *PickVariable*, *RepeatVariable*, *CompoundVariable*,
SliceVariable, *ModelVariable*

`BaseVariable.antidiag`

```
Variable::t antidiag()
Variable::t antidiag(int index)
```

Return the antidiagonal of a square variable matrix.

Parameters `index (int)` – Index of the anti-diagonal

Return (*Variable*)

`BaseVariable.asExpr`

```
Expression::t asExpr()
```

Create an *Expression* object corresponding to $I \cdot V$, where I is the identity matrix and V is this variable.

Return (*Expression*)

`BaseVariable.diag`

```
Variable::t diag()
Variable::t diag(int index)
```

Return the diagonal of a square variable matrix.

Parameters `index (int)` – Index of the anti-diagonal

Return (*Variable*)

`BaseVariable.dual`

```
shared_ptr<ndarray<double,1>> dual()
```

Get the dual solution value of the variable as an array. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

Return (`double[]`)

`BaseVariable.getModel`

```
Model::t getModel()
```

Return the model to which the variable belongs.

Return (*Model*)

`BaseVariable.getShape`

```
Set::t getShape()
```

Return the shape of the variable.

Return (*Set*)

BaseVariable.index

```
Variable::t index(int index)
Variable::t index(shared_ptr<ndarray<int,1>> index)
Variable::t index(int i0, int i1)
Variable::t index(int i0, int i1, int i2)
```

Return a variable slice of size 1 corresponding to a single element in the variable object..

Parameters

- `index (int)`
- `index (int[])`
- `i0 (int)` – Index in the first dimension of the element requested.
- `i1 (int)` – Index in the second dimension of the element requested.
- `i2 (int)` – Index in the second dimension of the element requested.

Return (*Variable*)

BaseVariable.level

```
shared_ptr<ndarray<double,1>> level()
```

Get the primal solution value of the variable as an array. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

Return (`double[]`)

BaseVariable.makeContinuous

```
void makeContinuous()
```

Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger

```
void makeInteger()
```

Apply integrality constraints on the variable.

BaseVariable.pick

```
Variable::t pick(shared_ptr<ndarray<int,1>> idxs)
Variable::t pick(shared_ptr<ndarray<int,2>> midxs)
Variable::t pick(shared_ptr<ndarray<int,1>> i0, shared_ptr<ndarray<int,1>> i1)
Variable::t pick(shared_ptr<ndarray<int,1>> i0, shared_ptr<ndarray<int,1>> i1, shared_ptr<
↪ ndarray<int,1>> i2)
```

Create a slice variable by picking a list of indexes from this variable.

Parameters

- `idxs (int[])` – Indexes of the elements requested.
- `midxs (int[][])` – Matrix of indexes of the elements requested.
- `i0 (int[])`
- `i1 (int[])` – Index along the first dimension.

- `i2 (int[])` – Index along the second dimension.

Return (*Variable*)

`BaseVariable.setLevel`

```
void setLevel(shared_ptr<ndarray<double,1>> v)
```

Set values for an initial solution for this variable. Note that these values are buffered until the solver is called; they are not available through the `level()` methods.

Parameters `v (double[])` – An array of values to be assigned to the variable.

`BaseVariable.shape`

```
Set::t shape()
```

Return the shape of the variable.

Return (*Set*)

`BaseVariable.size`

```
long long size()
```

Get the number of elements in the variable.

Return (`long long`)

`BaseVariable.slice`

```
Variable::t slice(int first, int last)
Variable::t slice(shared_ptr<ndarray<int,1>> first, shared_ptr<ndarray<int,1>> last)
```

Create a slice variable by picking a range of indexes for each variable dimension

Parameters

- `first (int)` – The index of the first element(s) of the slice.
- `first (int[])` – The index of the first element(s) of the slice.
- `last (int)` – The index after the last element of the slice.
- `last (int[])`

Return (*Variable*)

`BaseVariable.toString`

```
string toString()
```

Create a string representation of the variable.

Return (`string`)

`BaseVariable.transpose`

```
Variable::t transpose()
```

Note that this requires a one- or two-dimensional variable.

Return (*Variable*)

14.2.3 Class BoundInterfaceConstraint

`mosek::fusion::BoundInterfaceConstraint`

Interface to either the upper bound or the lower bound of a ranged constraint.

This class is never explicitly instantiated; it is created by a *RangedConstraint* to allow accessing a bound value and the dual variable value corresponding to the relevant bound as a separate object. The constraint

$$b_l \leq a^T x \leq b_u$$

has two bounds and two dual variables; these are not immediately available through the *RangedConstraint* object, but can be accessed through a *BoundInterfaceConstraint*.

Implements *SliceConstraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.toString – Create a human readable string representation of the constraint.

SliceConstraint.size – Get the total number of elements in the constraint.

SliceConstraint.slice – Create a slice constraint.

14.2.4 Class BoundInterfaceVariable

`mosek::fusion::BoundInterfaceVariable`

Interface to either the upper bound or the lower bound of a ranged variable.

This class is never explicitly instantiated; it is created by a *RangedVariable* to allow accessing a bound value and the dual variable value corresponding to the relevant bound as a separate object. The variable

$$b_l \leq x \leq b_u$$

has two bounds and two dual variables; these are not immediately available through the *RangedVariable* object, but can be accessed through a *BoundInterfaceVariable*.

Implements *SliceVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

SliceVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

14.2.5 Class CompoundConstraint

`mosek::fusion::CompoundConstraint`

Stacking of constraints.

A *CompoundConstraint* represents a stack of other variable objects and can be used as a 1-dimensional variable. The class is never explicitly instantiated, but is created using *Constraint.stack*.

As this class is derived from *Variable*, it may be used as a normal variable when creating expressions.

Implements *Constraint*

Members *CompoundConstraint.slice* – Unimplemented method!.

Constraint.add – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

Constraint.toString – Create a human readable string representation of the constraint.

`CompoundConstraint.slice`

```
Constraint::t slice(int first, int last)
Constraint::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Unimplemented method!.

Parameters

- **first** (int) – Index of the first element in the slice.
- **last** (int) – Index of the last element in the slice.

- `firsta (int[])` – Array of start elements in the slice.
- `lasta (int[])` – Array of end element in the slice.

Return (*Constraint*)

14.2.6 Class CompoundVariable

`mosek::fusion::CompoundVariable`

A stack of several other variables.

A compound variable represents a stack of other variable objects and can be used as a 1-dimensional variable. The class is never explicitly instantiated, but is created using *Var.stack*.

Implements *BaseVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

CompoundVariable.asExpr – Create an expression corresponding to the variable object.

CompoundVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

`CompoundVariable.asExpr`

<code>Expression::t asExpr()</code>

Create an *Expression* object corresponding to $I \cdot V$, where I is the identity matrix and V is this variable.

Return (*Expression*)

`CompoundVariable.slice`

```
Variable::t slice(int first, int last)
Variable::t slice(shared_ptr<ndarray<int,1>> first, shared_ptr<ndarray<int,1>> last)
```

Create a slice variable by picking a range of indexes for each variable dimension

Parameters

- `first (int)` – The index of the first element(s) of the slice.
- `first (int[])` – The index of the first element(s) of the slice.
- `last (int)` – The index after the last element of the slice.
- `last (int[])`

Return (*Variable*)

14.2.7 Class ConicConstraint

`mosek::fusion::ConicConstraint`

This class represents a conic constraint of the form

$$Ax - b \in \mathcal{K}$$

where \mathcal{K} is either a quadratic cone or a rotated quadratic cone. Then class is never explicitly instantiated, but is created using `Model.constraint` by specifying a conic domain.

Note that a conic constraint in *Fusion* is always *dense* in the sense that all member constraints are created in the underlying optimization problem immediately.

Implements *ModelConstraint*

Members *ConicConstraint.toString* – Create a human readable string representation of the constraint.

Constraint.add – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

ModelConstraint.slice – Create a slice constraint.

`ConicConstraint.toString`

```
string toString()
```

Create a human readable string representation of the constraint.

Return (*string*)

14.2.8 Class ConicVariable

`mosek::fusion::ConicVariable`

This class represents a conic variable of the form

$$Ax - b \in \mathcal{K}$$

where \mathcal{K} is either a quadratic cone or a rotated quadratic cone. Then class is never explicitly instantiated, but is created using `Model.variable` by specifying a conic domain.

Note that a conic variable in *Fusion* is always *dense* in the sense that all member variables are created in the underlying optimization problem immediately.

Implements `ModelVariable`

Members `BaseVariable.antidiag` – Return the antidiagonal of a square variable matrix.

`BaseVariable.asExpr` – Create an expression corresponding to the variable object.

`BaseVariable.diag` – Return the diagonal of a square variable matrix.

`BaseVariable.dual` – Get the dual solution value of the variable.

`BaseVariable.getModel` – Return the model to which the variable belongs.

`BaseVariable.getShape` – Return the shape of the variable.

`BaseVariable.index` – Return a variable slice of size 1 corresponding to a single element in the variable object..

`BaseVariable.level` – Get the primal solution value of the variable.

`BaseVariable.makeContinuous` – Drop integrality constraints on the variable, if any.

`BaseVariable.makeInteger` – Apply integrality constraints on the variable.

`BaseVariable.pick` – Create a slice variable by picking a list of indexes from this variable.

`BaseVariable.setLevel` – Input solution values for this variable

`BaseVariable.shape` – Return the shape of the variable.

`BaseVariable.size` – Get the number of elements in the variable.

`BaseVariable.transpose` – Transpose a vector or matrix variable

`ConicVariable.toString` – Create a string representation of the variable.

`ModelVariable.slice` – Create a slice variable by picking a range of indexes for each variable dimension

`ConicVariable.toString`

`string toString()`

Create a string representation of the variable.

Return (string)

14.2.9 Class Constraint

`mosek::fusion::Constraint`

An abstract constraint object. This is the base class for all constraint types in Fusion.

The *Constraint* object can be an interface to the normal model constraint, e.g. *LinearConstraint* and *ConicConstraint*, to slices of other constraints or to concatenations of other constraints.

Primal and dual solution values can be accessed through the *Constraint* object.

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

Constraint.slice – Create a slice constraint.

Constraint.toString – Create a human readable string representation of the constraint.

Static members *Constraint.stack* – Stack a number of constraints.

Implemented by *CompoundConstraint*, *ModelConstraint*, *SliceConstraint*

Constraint.add

```
Constraint::t add(Expression::t expr)
Constraint::t add(Variable::t v)
Constraint::t add(shared_ptr<ndarray<double,1>> cs)
Constraint::t add(double c)
```

Add an expression to the constraint expression. The added expression must have the same size and shape as the constraint.

Parameters

- *expr* (*Expression*) – An expression to add.
- *v* (*Variable*) – A variable to add.
- *cs* (*double[]*) – An array of constants to add.
- *c* (*double*) – A constant to add.

Return (*Constraint*)

Constraint.dual

```
shared_ptr<ndarray<double,1>> dual()
shared_ptr<ndarray<double,1>> dual(int firstidx, int lastidx)
shared_ptr<ndarray<double,1>> dual(shared_ptr<ndarray<int,1>> firstidxa, shared_ptr
↪ <ndarray<int,1>> lastidxa)
```

Get the dual solution values of the constraint or its slice. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

Parameters

- *firstidx* (*int*) – The index of the first element in the slice.
- *lastidx* (*int*) – The index of the last element of the slice plus one.
- *firstidxa* (*int[]*) – Multi-dimensional index of the first element in the slice.

- `lastidxa (int[])` – Multi-dimensional index of the element after the end of the slice.

Return (`double[]`)

`Constraint.get_model`

```
Model::t get_model()
```

Get the model to which the constraint belongs.

Return (`Model`)

`Constraint.get_nd`

```
int get_nd()
```

Get the number of dimensions of the constraint.

Return (`int`)

`Constraint.index`

```
Constraint::t index(int idx)
Constraint::t index(shared_ptr<ndarray<int,1>> idxa)
```

Get a single element from a one-dimensional constraint.

Parameters

- `idx (int)` – The index of the element.
- `idxa (int[])` – A multi-dimensional index of the element.

Return (`Constraint`)

`Constraint.level`

```
shared_ptr<ndarray<double,1>> level()
```

Get the primal solution values of the constraint. This amounts to evaluating the Ax part of the constraint expression for the relevant solution value. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

Return (`double[]`)

`Constraint.shape`

```
Set::t shape()
```

Return the constraint's shape.

Return (`Set`)

`Constraint.size`

```
long long size()
```

Get the total number of elements in the constraint.

Return (`long long`)

`Constraint.slice`

```
Constraint::t slice(int first, int last)
Constraint::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Create a slice constraint.

Parameters

- `first` (`int`) – Index of the first element in the slice.
- `last` (`int`) – Index of the first element after the end of the slice.
- `firsta` (`int[]`) – The indexes of first elements in the slice along each dimension.
- `lasta` (`int[]`) – The indexes of first elements after the end of the slice along each dimension.

Return (*Constraint*)

`Constraint.stack`

```
Constraint::t Constraint::stack(Constraint::t v1, Constraint::t v2)
Constraint::t Constraint::stack(Constraint::t v1, Constraint::t v2, Constraint::t v3)
Constraint::t Constraint::stack(shared_ptr<ndarray<Constraint::t,1>> clist)
```

Stack a number of constraints.

Parameters

- `v1` (*Constraint*) – The first constraint in the stack.
- `v2` (*Constraint*) – The second constraint in the stack.
- `v3` (*Constraint*) – The third constraint in the stack.
- `clist` (*Constraint[]*) – The constraints in the stack.

Return (*Constraint*)

`Constraint.toString`

```
string toString()
```

Create a human readable string representation of the constraint.

Return (`string`)

14.2.10 Class Domain

`mosek::fusion::Domain`

The *Domain* class defines a set of static method for creating various variable and constraint domains. A *Domain* object specifies a subset of \mathbb{R}^n , which can be used to define the feasible domain of variables and expressions.

For further details on the use of these, see *Model.variable* and *Model.constraint*.

Static members *Domain.axis* – Set the dimension along which the cones are created.

Domain.binary – Creates a domain of binary variables.

Domain.equalsTo – Defines the domain consisting of a fixed point.

Domain.greaterThan – Defines the domain specified by a lower bound in each dimension.

- Domain.inPSDCone* – Creates a domain of Positive Semidefinite matrices.
- Domain.inQCone* – Defines the domain of quadratic cones.
- Domain.inRange* – Creates a domain specified by a range in each dimension.
- Domain.inRotatedQCone* – Defines the domain of rotated quadratic cones.
- Domain.integral* – Creates a domain of integral variables.
- Domain.isLinPSD* – Creates a domain of Positive Semidefinite matrices.
- Domain.isTrilPSD* – Creates a domain of Positive Semidefinite matrices.
- Domain.lessThan* – Defines the domain specified by an upper bound in each dimension.
- Domain.sparse* – Ask to use a sparse representation.
- Domain.symmetric* – Impose symmetry on a given linear domain.
- Domain.unbounded* – Creates a domain in which variables are unbounded.

Domain.axis

```
QConeDomain::t Domain::axis(QConeDomain::t c, int a)
```

Set the dimension along which the cones are created. If this conic quadratic domain is used for a variable or expression of dimension d , then the conic constraint will be applicable to all vectors obtained by fixing the coordinates other than a -th and moving along the a -th coordinate. If $d = 2$ this can be used to define the conditions “every row of the matrix is in a cone” and “every column of a matrix is in a cone”.

The default is the last dimension $a = d - 1$.

Parameters

- c (*QConeDomain*) – A domain of quadratic cones.
- a (int) – The axis.

Return (*QConeDomain*)

Domain.binary

```
RangeDomain::t Domain::binary(int n)
RangeDomain::t Domain::binary(int m, int n)
RangeDomain::t Domain::binary(shared_ptr<ndarray<int,1>> dims)
RangeDomain::t Domain::binary()
```

Create a domain of binary variables.

Parameters

- n (int) – Dimension size.
- m (int) – Dimension size.
- $dims$ (int[]) – A list of dimension sizes.

Return (*RangeDomain*)

Domain.equalsTo

```
LinearDomain::t Domain::equalsTo(double b)
LinearDomain::t Domain::equalsTo(double b, int n)
LinearDomain::t Domain::equalsTo(double b, int m, int n)
LinearDomain::t Domain::equalsTo(double b, shared_ptr<ndarray<int,1>> dims)
```

```

LinearDomain::t Domain::equalsTo(shared_ptr<ndarray<double,1>> a1)
LinearDomain::t Domain::equalsTo(shared_ptr<ndarray<double,2>> a2)
LinearDomain::t Domain::equalsTo(shared_ptr<ndarray<double,1>> a1, shared_ptr<ndarray<int,
↪1>> dims)
LinearDomain::t Domain::equalsTo(Matrix::t mx)

```

Defines the domain consisting of a fixed point.

Parameters

- **b** (`double`) – A single value. This is scalable: it means that each element in the variable or constraint is fixed to *b*.
- **n** (`int`) – Dimension size.
- **m** (`int`) – Dimension size.
- **dims** (`int[]`) – A list of dimension sizes.
- **a1** (`double[]`) – A one-dimensional array of bounds. The shape must match the variable or constraint with which it is used.
- **a2** (`double[][]`) – A two-dimensional array of bounds. The shape must match the variable or constraint with which it is used.
- **mx** (*Matrix*) – A matrix of bound values. The shape must match the variable or constraint with which it is used.

Return (*LinearDomain*)

`Domain.greaterThan`

```

LinearDomain::t Domain::greaterThan(double b)
LinearDomain::t Domain::greaterThan(double b, int n)
LinearDomain::t Domain::greaterThan(double b, int m, int n)
LinearDomain::t Domain::greaterThan(double b, shared_ptr<ndarray<int,1>> dims)
LinearDomain::t Domain::greaterThan(shared_ptr<ndarray<double,1>> a1)
LinearDomain::t Domain::greaterThan(shared_ptr<ndarray<double,2>> a2)
LinearDomain::t Domain::greaterThan(shared_ptr<ndarray<double,1>> a1, shared_ptr<ndarray
↪<int,1>> dims)
LinearDomain::t Domain::greaterThan(Matrix::t mx)

```

Defines the domain specified by a lower bound in each dimension.

Parameters

- **b** (`double`) – A single value. This is scalable: it means that each element in the variable or constraint is greater than or equal to *b*.
- **n** (`int`) – Dimension size.
- **m** (`int`) – Dimension size.
- **dims** (`int[]`) – A list of dimension sizes.
- **a1** (`double[]`) – A one-dimensional array of bounds. The shape must match the variable or constraint with which it is used.
- **a2** (`double[][]`) – A two-dimensional array of bounds. The shape must match the variable or constraint with which it is used.
- **mx** (*Matrix*) – A matrix of bound values. The shape must match the variable or constraint with which it is used.

Return (*LinearDomain*)

`Domain.inPSDCone`

```

PSDDomain::t Domain::inPSDCone()
PSDDomain::t Domain::inPSDCone(int n)
PSDDomain::t Domain::inPSDCone(int n, int m)

```

Creates an object representing a cone of the form

$$\left\{ X \in \mathbb{R}^{n \times n} : \frac{1}{2}(X + X^T) \in \mathcal{S}_+^n \right\}.$$

i.e. a positive semidefinite matrix. The shape of the result is $n \times n$. If m was given the domain is a product of m such cones, that is of shape $n \times n \times m$.

When used to create a new variable in *Model.variable* it additionally imposes symmetry, so the new variable is symmetric positive semidefinite.

Parameters

- **n** (int) – Dimension of the PSD matrix.
- **m** (int) – Number of matrices (default 1).

Return (*PSDDomain*)

Domain.inQCone

```

QConeDomain::t Domain::inQCone()
QConeDomain::t Domain::inQCone(int n)
QConeDomain::t Domain::inQCone(int m, int n)
QConeDomain::t Domain::inQCone(shared_ptr<ndarray<double,1>> dims)

```

Defines the domain of quadratic cones:

$$\left\{ x \in \mathbb{R}^n : x_1^2 \geq \sum_{i=2}^n x_i^2, x_1 \geq 0 \right\}$$

The conic domain scales as follows. If a variable or expression constrained to a quadratic cone is not a single vector but a d -dimensional variable then the conic domain is applicable to all vectors obtained by fixing the first $d - 1$ coordinates and moving along the last coordinate. If $d = 2$ it means that each row of a matrix must belong to a cone. See also *Domain.axis*.

If m was given the domain is a product of m such cones.

Parameters

- **n** (int) – The size of each cone; at least 2.
- **m** (int) – The number of cones (default 1).
- **dims** (int[]) – Shape of the domain.

Return (*QConeDomain*)

Domain.inRange

```

RangeDomain::t Domain::inRange(double lb, double ub)
RangeDomain::t Domain::inRange(double lb, shared_ptr<ndarray<double,1>> uba)
RangeDomain::t Domain::inRange(shared_ptr<ndarray<double,1>> lba, double ub)
RangeDomain::t Domain::inRange(shared_ptr<ndarray<double,1>> lba, shared_ptr<ndarray<double,1>> uba)
RangeDomain::t Domain::inRange(double lb, Matrix::t ubm)
RangeDomain::t Domain::inRange(Matrix::t lbm, double ub)
RangeDomain::t Domain::inRange(Matrix::t lbm, Matrix::t ubm)

```

Creates a domain specified by a range in each dimension.

Parameters

- `lb (double)` – The lower bound as a common scalar value.
- `ub (double)` – The upper bound as a common scalar value.
- `uba (double[])` – The upper bounds as an array.
- `lba (double[])` – The lower bounds as an array.
- `ubm (Matrix)` – The upper bounds as a *Matrix* object.
- `lbm (Matrix)` – The lower bounds as a *Matrix* object.

Return (*RangeDomain*)

Domain.inRotatedQCone

```
QConeDomain::t Domain::inRotatedQCone()
QConeDomain::t Domain::inRotatedQCone(int n)
QConeDomain::t Domain::inRotatedQCone(int m, int n)
QConeDomain::t Domain::inRotatedQCone(shared_ptr<ndarray<int,1>> dims)
```

Defines the domain of rotated quadratic cones:

$$\left\{ x \in \mathbb{R}^n : 2x_1x_2 \geq \sum_{i=3}^n x_i^2, x_1, x_2 \geq 0 \right\}$$

The conic domain scales as follows. If a variable or expression constrained to a quadratic cone is not a single vector but a d -dimensional variable then the conic domain is applicable to all vectors obtained by fixing the first $d - 1$ coordinates and moving along the last coordinate. If $d = 2$ it means that each row of a matrix must belong to a cone. See also *Domain.axis*.

If m was given the domain is a product of m such cones.

Parameters

- `n (int)` – The size of each cone; at least 3.
- `m (int)` – The number of cones (default 1).
- `dims (int[])` – Shape of the domain.

Return (*QConeDomain*)

Domain.integral

```
QConeDomain::t Domain::integral(QConeDomain::t c)
LinearDomain::t Domain::integral(LinearDomain::t ld)
RangeDomain::t Domain::integral(RangeDomain::t rd)
```

Modify a given domain restricting its elements to be integral.

Parameters

- `c (QConeDomain)` – A conic quadratic domain.
- `ld (LinearDomain)` – A linear domain.
- `rd (RangeDomain)` – A ranged domain.

Return

- (*QConeDomain*)
- (*LinearDomain*)
- (*RangeDomain*)

Domain.isLinPSD

```

LinPSDDomain::t Domain::isLinPSD()
LinPSDDomain::t Domain::isLinPSD(int n)
LinPSDDomain::t Domain::isLinPSD(int n, int m)

```

Creates an domain of vectors of length $\frac{1}{2}n(n+1)$ which are the flattenings of the lower-triangular part of a symmetric positive-semidefinite matrix X . The shape of the result is $\frac{1}{2}n(n+1)$. If m was given the domain is a product of m such domains, that is of shape $\frac{1}{2}n(n+1)m$.

Parameters

- **n** (int) – Dimension of the PSD matrix.
- **m** (int) – Number of matrices (default 1).

Return (*LinPSDDomain*)

Domain.isTrilPSD

```

PSDDomain::t Domain::isTrilPSD()
PSDDomain::t Domain::isTrilPSD(int n)
PSDDomain::t Domain::isTrilPSD(int n, int m)

```

Creates an object representing a cone of the form

$$\{X \in \mathbb{R}^{n \times n} : \text{tril}(X) \in \mathcal{S}_+^n\}.$$

i.e. the lower triangular part of X defines the symmetric matrix that is positive semidefinite. The shape of the result is $n \times n$. If m was given the domain is a product of m such cones, that is of shape $n \times n \times m$.

Parameters

- **n** (int) – Dimension of the PSD matrix.
- **m** (int) – Number of matrices (default 1).

Return (*PSDDomain*)

Domain.lessThan

```

LinearDomain::t Domain::lessThan(double b)
LinearDomain::t Domain::lessThan(double b, int n)
LinearDomain::t Domain::lessThan(double b, int m, int n)
LinearDomain::t Domain::lessThan(double b, shared_ptr<ndarray<int,1>> dims)
LinearDomain::t Domain::lessThan(shared_ptr<ndarray<double,1>> a1)
LinearDomain::t Domain::lessThan(shared_ptr<ndarray<double,2>> a2)
LinearDomain::t Domain::lessThan(shared_ptr<ndarray<double,1>> a1, shared_ptr<ndarray<int,
↪1>> dims)
LinearDomain::t Domain::lessThan(Matrix::t mx)

```

Defines the domain specified by an upper bound in each dimension.

Parameters

- **b** (double) – A single value. This is scalable: it means that each element in the variable or constraint is less than or equal to b .
- **n** (int) – Dimension size.
- **m** (int) – Dimension size.
- **dims** (int[]) – A list of dimension sizes.

- **a1** (`double[]`) – A one-dimensional array of bounds. The shape must match the variable or constraint with which it is used.
- **a2** (`double[][]`) – A two-dimensional array of bounds. The shape must match the variable or constraint with which it is used.
- **mx** (*Matrix*) – A matrix of bound values. The shape must match the variable or constraint with which it is used.

Return (*LinearDomain*)

`Domain.sparse`

```
LinearDomain::t Domain::sparse(LinearDomain::t ld)
RangeDomain::t Domain::sparse(RangeDomain::t rd)
```

Given a linear domain, this method explicitly suggest to *Fusion* that a sparse representation is helpful.

Parameters

- **ld** (*LinearDomain*) – The putative linear sparse domain.
- **rd** (*RangeDomain*) – The putative ranged sparse domain.

Return

- (*LinearDomain*)
- (*RangeDomain*)

`Domain.symmetric`

```
SymmetricLinearDomain::t Domain::symmetric(LinearDomain::t ld)
SymmetricRangeDomain::t Domain::symmetric(RangeDomain::t rd)
```

Given a linear domain D whose shape is that of square matrices, this method returns a domain consisting of symmetric matrices in D .

Parameters

- **ld** (*LinearDomain*) – The linear domain to be symmetrized.
- **rd** (*RangeDomain*) – The ranged domain to be symmetrized.

Return

- (*SymmetricLinearDomain*)
- (*SymmetricRangeDomain*)

`Domain.unbounded`

```
LinearDomain::t Domain::unbounded()
LinearDomain::t Domain::unbounded(int n)
LinearDomain::t Domain::unbounded(int m, int n)
LinearDomain::t Domain::unbounded(shared_ptr<ndarray<int,1>> dims)
```

Creates a domain in which variables are unbounded.

Parameters

- **n** (`int`) – Dimension size.
- **m** (`int`) – Dimension size.
- **dims** (`int[]`) – A list of dimension sizes.

Return (*LinearDomain*)

14.2.11 Class Expr

`mosek::fusion::Expr`

It represents an expression of the form $Ax + b$, where A is a matrix on sparse form, x is a variable vector and b is a vector of scalars.

Additionally, the class defines a set of static methods for constructing and manipulating various expressions.

Members *Expr.eval* – Evaluate the expression info to a simple array-based form.

Expr.getModel – Return the model to which the expression belongs

Expr.getShape – Return the shape of the expression

Expr.index – Return a specific term of the expression.

Expr.numNonzeros – Return the number of non-zero elements in the expression.

Expr.pick – Pick elements from this expression.

Expr.shape – Get the shape of the expression.

Expr.size – Return the expression size.

Expr.slice – Return a slice of the expression.

Expr.toString – Create a human readable string representation of the expression.

Expr.transpose – Transpose the expression.

Static members *Expr.add* – Compute the sum of expressions.

Expr.constTerm – Create an expression consisting of a constant vector of values.

Expr.dot – Return a scalar expression object representing the dot-product of two items.

Expr.flatten – Reshape the expression into a vector.

Expr.hstack – Stack a list of expressions horizontally (i.e. along the second dimension).

Expr.mul – Multiply two items.

Expr.mulDiag – Compute the diagonal of the product of two matrices.

Expr.mulElem – Element-wise product of two items.

Expr.neg – Change the sign of an expression

Expr.ones – Create a vector of ones as an expression.

Expr.outer – Return the outer-product of two vectors.

Expr.repeat – Repeat an expression a number of times in the given dimension.

Expr.reshape – Reshape the expression into a different shape with the same number of elements.

Expr.stack – Stack a list of expressions in an arbitrary dimension.

Expr.sub – Compute the difference of two expressions.

Expr.sum – Sum the elements of an expression.

Expr.vstack – Stack a list of expressions vertically (i.e. along the first dimension).

Expr.zeros – Create a vector of zeros as an expression.

Expr.add

```

Expression::t Expr::add(Expression::t e1, Expression::t e2)
Expression::t Expr::add(Expression::t e1, Variable::t v2)
Expression::t Expr::add(Variable::t v1, Expression::t e2)
Expression::t Expr::add(Expression::t e1, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::add(Expression::t e1, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::add(shared_ptr<ndarray<double,1>> a1, Expression::t e2)
Expression::t Expr::add(shared_ptr<ndarray<double,2>> a2, Expression::t e2)
Expression::t Expr::add(Expression::t e1, double c)
Expression::t Expr::add(double c, Expression::t e2)
Expression::t Expr::add(Expression::t e1, Matrix::t m)
Expression::t Expr::add(Matrix::t m, Expression::t e2)
Expression::t Expr::add(Expression::t e1, NDSparseArray::t n)
Expression::t Expr::add(NDSparseArray::t n, Expression::t e2)
Expression::t Expr::add(Variable::t v1, Variable::t v2)
Expression::t Expr::add(Variable::t v1, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::add(Variable::t v1, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::add(shared_ptr<ndarray<double,1>> a1, Variable::t v2)
Expression::t Expr::add(shared_ptr<ndarray<double,2>> a2, Variable::t v2)
Expression::t Expr::add(Variable::t v1, double c)
Expression::t Expr::add(double c, Variable::t v2)
Expression::t Expr::add(Variable::t v1, Matrix::t m)
Expression::t Expr::add(Matrix::t m, Variable::t v2)
Expression::t Expr::add(Variable::t v1, NDSparseArray::t n)
Expression::t Expr::add(NDSparseArray::t n, Variable::t v2)
Expression::t Expr::add(shared_ptr<ndarray<Variable::t,1>> vs)
Expression::t Expr::add(shared_ptr<ndarray<Expression::t,1>> exps)

```

Computes the sum of two or more expressions or variables. The following types of arguments are allowed:

A	B
Variable	Variable
Expression	Expression
double	
double[]	
double[,]	
Matrix	
NDSparseArray	

By symmetry both `add(A,B)` and `add(B,A)` are available.

The arguments must have the same shapes and the returned expression also has that shape. If one of the arguments is a single scalar, it is promoted to the shape that matches the shape of the other argument, i.e. the scalar is added to all entries of the other argument.

Parameters

- `e1` (*Expression*) – An expression.
- `e2` (*Expression*) – An expression.
- `v2` (*Variable*) – A variable.
- `v1` (*Variable*) – A variable.
- `a1` (`double[]`) – A one-dimensional array of constants.
- `a2` (`double[][]`) – A two-dimensional array of constants.
- `c` (`double`) – A constant.
- `m` (*Matrix*) – A Matrix object.

- **n** (*NDSparseArray*) – An *NDSparseArray* object.
- **vs** (*Variable*[]) – A list of variables. All variables in the array must have the same shape. The list must contain at least one element.
- **exps** (*Expression*[]) – A list of expressions. All expressions in the array must have the same shape. The list must contain at least one element.

Return (*Expression*)

`Expr.constTerm`

```
Expression::t Expr::constTerm(shared_ptr<ndarray<double,1>> vals1)
Expression::t Expr::constTerm(shared_ptr<ndarray<double,2>> vals2)
Expression::t Expr::constTerm(int size, double val)
Expression::t Expr::constTerm(Set::t shp, double val)
Expression::t Expr::constTerm(double val)
Expression::t Expr::constTerm(Matrix::t m)
Expression::t Expr::constTerm(NDSparseArray::t nda)
```

Create an expression consisting of a constant vector of values.

Parameters

- **vals1** (*double*[]) – A vector initializing the expression.
- **vals2** (*double*[][][]) – A two-dimensional array initializing the expression.
- **size** (*int*) – Length of the vector to be constructed.
- **val** (*double*) – A scalar value to be repeated in all entries of the expression.
- **shp** (*Set*) – Defines the shape of the expression.
- **m** (*Matrix*) – A Matrix of values initializing the expression.
- **nda** (*NDSparseArray*) – An multi-dimensional sparse array initializing the expression.

Return (*Expression*)

`Expr.dot`

```
Expression::t Expr::dot(Variable::t v, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::dot(Variable::t v, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::dot(Variable::t v, Matrix::t m)
Expression::t Expr::dot(Variable::t v, NDSparseArray::t spm)
Expression::t Expr::dot(Expression::t expr, NDSparseArray::t spm)
Expression::t Expr::dot(Expression::t expr, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::dot(Expression::t expr, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::dot(Expression::t expr, Matrix::t m)
Expression::t Expr::dot(shared_ptr<ndarray<double,1>> a1, Expression::t expr)
Expression::t Expr::dot(shared_ptr<ndarray<double,1>> a1, Variable::t v)
Expression::t Expr::dot(shared_ptr<ndarray<double,2>> a2, Expression::t expr)
Expression::t Expr::dot(shared_ptr<ndarray<double,2>> a2, Variable::t v)
Expression::t Expr::dot(NDSparseArray::t spm, Expression::t expr)
Expression::t Expr::dot(NDSparseArray::t spm, Variable::t v)
Expression::t Expr::dot(Matrix::t m, Variable::t v)
Expression::t Expr::dot(Matrix::t m, Expression::t expr)
```

Return an object representing the inner product (dot product) $x^T y = \sum_{i=1}^n x_i y_i$ of two objects x, y of size n .

Both arguments must have the same length when flattened. In particular, they can be two vectors of the same length or two matrices of the same shape.

Parameters

- v (*Variable*) – A variable object.
- $a1$ (`double[]`) – A one-dimensional coefficient array.
- $a2$ (`double[][]`) – A two-dimensional coefficient array.
- m (*Matrix*) – A matrix object.
- spm (*NDSparseArray*) – A multidimensional sparse array object.
- $expr$ (*Expression*) – An expression object.

Return (*Expression*)`Expr.eval`

```
FlatExpr::t eval()
```

Evaluate the expression info to a simple array-based form.

Return (*FlatExpr*)`Expr.flatten`

```
Expression::t Expr::flatten(Expression::t e)
```

Reshape the expression into a vector.

Parameters e (*Expression*)**Return** (*Expression*)`Expr.getModel`

```
Model::t getModel()
```

Return the model to which the expression belongs

Return (*Model*)`Expr.getShape`

```
Set::t getShape()
```

Return the shape of the expression

Return (*Set*)`Expr.hstack`

```
Expression::t Expr::hstack(shared_ptr<ndarray<Expression::t,1>> exprs)
Expression::t Expr::hstack(Expression::t e1, Expression::t e2)
Expression::t Expr::hstack(Expression::t e1, double a2)
Expression::t Expr::hstack(Expression::t e1, Variable::t v2)
Expression::t Expr::hstack(double a1, Variable::t v2)
Expression::t Expr::hstack(double a1, Expression::t e2)
Expression::t Expr::hstack(Variable::t v1, double a2)
Expression::t Expr::hstack(Variable::t v1, Variable::t v2)
Expression::t Expr::hstack(Variable::t v1, Expression::t e2)
Expression::t Expr::hstack(double a1, double a2, Variable::t v3)
Expression::t Expr::hstack(double a1, double a2, Expression::t e3)
Expression::t Expr::hstack(double a1, Variable::t v2, double a3)
```

```

Expression::t Expr::hstack(double a1, Variable::t v2, Variable::t v3)
Expression::t Expr::hstack(double a1, Variable::t v2, Expression::t e3)
Expression::t Expr::hstack(double a1, Expression::t e2, double a3)
Expression::t Expr::hstack(double a1, Expression::t e2, Variable::t v3)
Expression::t Expr::hstack(double a1, Expression::t e2, Expression::t e3)
Expression::t Expr::hstack(Variable::t v1, double a2, double a3)
Expression::t Expr::hstack(Variable::t v1, double a2, Variable::t v3)
Expression::t Expr::hstack(Variable::t v1, double a2, Expression::t e3)
Expression::t Expr::hstack(Variable::t v1, Variable::t v2, double a3)
Expression::t Expr::hstack(Variable::t v1, Variable::t v2, Variable::t v3)
Expression::t Expr::hstack(Variable::t v1, Variable::t v2, Expression::t e3)
Expression::t Expr::hstack(Variable::t v1, Expression::t e2, double a3)
Expression::t Expr::hstack(Variable::t v1, Expression::t e2, Variable::t v3)
Expression::t Expr::hstack(Variable::t v1, Expression::t e2, Expression::t e3)
Expression::t Expr::hstack(Expression::t e1, double a2, double a3)
Expression::t Expr::hstack(Expression::t e1, double a2, Variable::t v3)
Expression::t Expr::hstack(Expression::t e1, double a2, Expression::t e3)
Expression::t Expr::hstack(Expression::t e1, Variable::t v2, double a3)
Expression::t Expr::hstack(Expression::t e1, Variable::t v2, Variable::t v3)
Expression::t Expr::hstack(Expression::t e1, Variable::t v2, Expression::t e3)
Expression::t Expr::hstack(Expression::t e1, Expression::t e2, double a3)
Expression::t Expr::hstack(Expression::t e1, Expression::t e2, Variable::t v3)
Expression::t Expr::hstack(Expression::t e1, Expression::t e2, Expression::t e3)

```

Stack a list of expressions horizontally (i.e. along the second dimension). The expressions must have the same shape, except for the second dimension. The arguments may be any combination of expressions, scalar constants and variables.

For example, if x^1, x^2, x^3 are three vectors of length n then their horizontal stack is the matrix

$$\begin{bmatrix} | & | & | \\ x^1 & x^2 & x^3 \\ | & | & | \end{bmatrix}$$

of shape $(n,3)$.

Parameters

- `exprs` (*Expression*[]) – A list of expressions.
- `e1` (*Expression*) – An expression.
- `e2` (*Expression*) – An expression.
- `a2` (double) – A scalar constant.
- `v2` (*Variable*) – A variable.
- `a1` (double) – A scalar constant.
- `v1` (*Variable*) – A variable.
- `v3` (*Variable*) – A variable.
- `e3` (*Expression*) – An expression.
- `a3` (double) – A scalar constant.

Return (*Expression*)

`Expr.index`

```

Expression::t index(int first)
Expression::t index(shared_ptr<ndarray<int,1>> firsta)

```

Return a specific term of the expression.

Parameters

- `first` (`int`) – The index of the term in a one-dimensional expression.
- `firsta` (`int[]`) – The indices of the term in a multi-dimensional expression.

Return (*Expression*)`Expr.mul`

```

Expression::t Expr::mul(Matrix::t mx, Variable::t v)
Expression::t Expr::mul(Variable::t v, Matrix::t mx)
Expression::t Expr::mul(Variable::t v, shared_ptr<ndarray<double,1>> vals)
Expression::t Expr::mul(shared_ptr<ndarray<double,1>> vals, Variable::t v)
Expression::t Expr::mul(double val, Variable::t v)
Expression::t Expr::mul(Variable::t v, double val)
Expression::t Expr::mul(shared_ptr<ndarray<double,2>> vals2, Variable::t v)
Expression::t Expr::mul(Variable::t v, shared_ptr<ndarray<double,2>> vals2)
Expression::t Expr::mul(Expression::t expr, double val)
Expression::t Expr::mul(double val, Expression::t expr)
Expression::t Expr::mul(shared_ptr<ndarray<double,1>> vals, Expression::t expr)
Expression::t Expr::mul(Expression::t expr, shared_ptr<ndarray<double,1>> vals)
Expression::t Expr::mul(Expression::t expr, Matrix::t mx)
Expression::t Expr::mul(Matrix::t mx, Expression::t expr)

```

Compute the product (in the sense of matrix multiplication or scalar-by-matrix multiplication) of two arguments.

The operands must be at most two-dimensional. One of the arguments must be a constant, a vector of constants or a matrix of constants. The other argument can be a variable or expression. This allows to produce matrix expressions where the entries are linear combinations of variables.

The size and shape of the arguments must adhere to the rules of linear algebra.

Parameters

- `mx` (*Matrix*) – A matrix.
- `v` (*Variable*) – A variable.
- `vals` (`double[]`) – A vector of scalars.
- `val` (`double`) – A scalar value.
- `vals2` (`double[][]`) – An array of scalars.
- `expr` (*Expression*) – An expression.

Return (*Expression*)`Expr.mulDiag`

```

Expression::t Expr::mulDiag(shared_ptr<ndarray<double,2>> a, Expression::t expr)
Expression::t Expr::mulDiag(Expression::t expr, shared_ptr<ndarray<double,2>> a)
Expression::t Expr::mulDiag(shared_ptr<ndarray<double,2>> a, Variable::t v)
Expression::t Expr::mulDiag(Variable::t v, shared_ptr<ndarray<double,2>> a)
Expression::t Expr::mulDiag(Matrix::t mx, Expression::t expr)
Expression::t Expr::mulDiag(Expression::t expr, Matrix::t mx)
Expression::t Expr::mulDiag(Matrix::t mx, Variable::t v)
Expression::t Expr::mulDiag(Variable::t v, Matrix::t mx)

```

Compute the diagonal of the product of two matrices. If $A \in \mathbb{M}(m, n)$ and $B \in \mathbb{M}(n, p)$, the result is a vector expression of length n equal to $\text{diag}(AB)$.

Parameters

- `a` (`double[][]`) – A constant matrix.

- `expr` (*Expression*) – An expression object.
- `v` (*Variable*) – A variable object.
- `mx` (*Matrix*) – A matrix object.

Return (*Expression*)

`Expr.mulElm`

```
Expression::t Expr::mulElm(Variable::t v, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::mulElm(Variable::t v, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::mulElm(Variable::t v, NDSparseArray::t spm)
Expression::t Expr::mulElm(Variable::t v, Matrix::t m)
Expression::t Expr::mulElm(Expression::t expr, NDSparseArray::t spm)
Expression::t Expr::mulElm(Expression::t expr, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::mulElm(Expression::t expr, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::mulElm(Expression::t expr, Matrix::t m)
Expression::t Expr::mulElm(shared_ptr<ndarray<double,1>> a1, Expression::t expr)
Expression::t Expr::mulElm(shared_ptr<ndarray<double,1>> a1, Variable::t v)
Expression::t Expr::mulElm(shared_ptr<ndarray<double,2>> a2, Expression::t expr)
Expression::t Expr::mulElm(shared_ptr<ndarray<double,2>> a2, Variable::t v)
Expression::t Expr::mulElm(NDSparseArray::t spm, Expression::t expr)
Expression::t Expr::mulElm(NDSparseArray::t spm, Variable::t v)
Expression::t Expr::mulElm(Matrix::t m, Variable::t v)
Expression::t Expr::mulElm(Matrix::t m, Expression::t expr)
```

Returns the element-wise product of two items. The two operands must have the same shape and the returned expression also has this shape.

Parameters

- `v` (*Variable*) – A variable object.
- `a1` (`double[]`) – A one-dimensional coefficient array.
- `a2` (`double[][]`) – A two-dimensional coefficient array.
- `spm` (*NDSparseArray*) – A multidimensional sparse array object.
- `m` (*Matrix*) – A matrix object.
- `expr` (*Expression*) – An expression object.

Return (*Expression*)

`Expr.neg`

```
Expression::t Expr::neg(Expression::t e)
Expression::t Expr::neg(Variable::t v)
```

Return a new expression object representing the given one with opposite sign.

Parameters

- `e` (*Expression*) – An expression object.
- `v` (*Variable*) – A variable object.

Return (*Expression*)

`Expr.numNonzeros`

```
long long numNonzeros()
```

Return the number of non-zero elements in the expression.

Return (long long)

Expr.ones

```
Expression::t Expr::ones(int num)
```

Create a vector of ones as an expression.

Parameters num (int) – The size of the expression.

Return (*Expression*)

Expr.outer

```
Expression::t Expr::outer(Variable::t v, shared_ptr<ndarray<double,1>> a)
Expression::t Expr::outer(shared_ptr<ndarray<double,1>> a, Variable::t v)
Expression::t Expr::outer(Variable::t v, Matrix::t m)
Expression::t Expr::outer(Matrix::t m, Variable::t v)
Expression::t Expr::outer(Expression::t e, shared_ptr<ndarray<double,1>> a)
Expression::t Expr::outer(shared_ptr<ndarray<double,1>> a, Expression::t e)
```

Return an expression representing the outer product xy^T of two vectors x, y . If x has length k and y has length n then the result is of shape (k, n) .

Parameters

- v (*Variable*) – A vector variable.
- a (double[]) – A vector of constants.
- m (*Matrix*) – A one-dimensional matrix.
- e (*Expression*) – A vector expression.

Return (*Expression*)

Expr.pick

```
Expression::t pick(shared_ptr<ndarray<int,1>> indexes)
Expression::t pick(shared_ptr<ndarray<int,2>> indexrows)
```

Creates a vector expression by picking elements from the current expression.

Parameters

- indexes (int[]) – A list of indices specifying positions in a one-dimensional expression.
- indexrows (int[][]) – A $n \times m$ array of integers where each row specifies an m -dimensional index to pick from an m -dimensional expression.

Return (*Expression*)

Expr.repeat

```
Expression::t Expr::repeat(Expression::t e, int n, int d)
```

Repeat an expression a number of times in the given dimension. This is equivalent to stacking n copies of the expression in dimension d ; see [Expr.stack](#).

Parameters

- e (*Expression*) – The expression to repeat.
- n (int) – Number of times to repeat. Must be strictly positive.

- `d (int)` – The dimension in which to repeat. Must define a valid dimension index.

Return (*Expression*)

`Expr.reshape`

```
Expression::t Expr::reshape(Expression::t e, Set::t shp)
Expression::t Expr::reshape(Expression::t e, int size)
Expression::t Expr::reshape(Expression::t e, int dimi, int dimj)
```

Reshape the expression into a different shape with the same number of elements.

Parameters

- `e (Expression)` – The expression to reshape.
- `shp (Set)` – The new shape of the expression; this must have the same total size as the old shape.
- `size (int)` – Reshape into a one-dimensional expression of this size.
- `dimi (int)` – The first dimension size.
- `dimj (int)` – The second dimension size.

Return (*Expression*)

`Expr.shape`

```
Set::t shape()
```

Get the shape of the expression.

Return (*Set*)

`Expr.size`

```
long long size()
```

Return the expression size, i.e. the product of the lengths along each dimension.

Return (`long long`)

`Expr.slice`

```
Expression::t slice(int first, int last)
Expression::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Return a slice of the expression.

Parameters

- `first (int)` – The index from which the slice begins.
- `last (int)` – The index after the last element of the slice.
- `firsta (int[])` – The indices from which the slice of a multidimensional expression begins.
- `lasta (int[])` – The indices after the last element of slice of a multidimensional expression.

Return (*Expression*)

Expr.stack

```

Expression::t Expr::stack(int dim, shared_ptr<ndarray<Expression::t,1>> exprs)
Expression::t Expr::stack(int dim, Expression::t e1, Expression::t e2)
Expression::t Expr::stack(int dim, Expression::t e1, double a2)
Expression::t Expr::stack(int dim, Expression::t e1, Variable::t v2)
Expression::t Expr::stack(int dim, double a1, Variable::t v2)
Expression::t Expr::stack(int dim, double a1, Expression::t e2)
Expression::t Expr::stack(int dim, Variable::t v1, double a2)
Expression::t Expr::stack(int dim, Variable::t v1, Variable::t v2)
Expression::t Expr::stack(int dim, Variable::t v1, Expression::t e2)
Expression::t Expr::stack(int dim, double a1, double a2, Variable::t v1)
Expression::t Expr::stack(int dim, double a1, double a2, Expression::t e1)
Expression::t Expr::stack(int dim, double a1, Variable::t v2, double a3)
Expression::t Expr::stack(int dim, double a1, Variable::t v2, Variable::t v3)
Expression::t Expr::stack(int dim, double a1, Variable::t v2, Expression::t e3)
Expression::t Expr::stack(int dim, double a1, Expression::t e2, double a3)
Expression::t Expr::stack(int dim, double a1, Expression::t e2, Variable::t v3)
Expression::t Expr::stack(int dim, double a1, Expression::t e2, Expression::t e3)
Expression::t Expr::stack(int dim, Variable::t v1, double a2, double a3)
Expression::t Expr::stack(int dim, Variable::t v1, double a2, Variable::t v3)
Expression::t Expr::stack(int dim, Variable::t v1, double a2, Expression::t e3)
Expression::t Expr::stack(int dim, Variable::t v1, Variable::t v2, double a3)
Expression::t Expr::stack(int dim, Variable::t v1, Variable::t v2, Variable::t v3)
Expression::t Expr::stack(int dim, Variable::t v1, Variable::t v2, Expression::t e3)
Expression::t Expr::stack(int dim, Variable::t v1, Expression::t e2, double a3)
Expression::t Expr::stack(int dim, Variable::t v1, Expression::t e2, Variable::t v3)
Expression::t Expr::stack(int dim, Variable::t v1, Expression::t e2, Expression::t e3)
Expression::t Expr::stack(int dim, Expression::t e1, double a2, double a3)
Expression::t Expr::stack(int dim, Expression::t e1, double a2, Variable::t v3)
Expression::t Expr::stack(int dim, Expression::t e1, double a2, Expression::t e3)
Expression::t Expr::stack(int dim, Expression::t e1, Variable::t v2, double a3)
Expression::t Expr::stack(int dim, Expression::t e1, Variable::t v2, Variable::t v3)
Expression::t Expr::stack(int dim, Expression::t e1, Variable::t v2, Expression::t e3)
Expression::t Expr::stack(int dim, Expression::t e1, Expression::t e2, double a3)
Expression::t Expr::stack(int dim, Expression::t e1, Expression::t e2, Variable::t v3)
Expression::t Expr::stack(int dim, Expression::t e1, Expression::t e2, Expression::t e3)
Expression::t Expr::stack(shared_ptr<ndarray<Expression::t,2>> exprs)

```

Stack a list of expressions along an arbitrary dimension. All expressions must have the same shape, except for dimension `dim`. The arguments may be any combination of expressions, scalar constants and variables.

For example, suppose A, B are two $n \times m$ matrices. Then stacking them in the first dimension produces a matrix of shape $(2n, m)$:

$$\begin{bmatrix} A \\ B \end{bmatrix},$$

stacking them in the second dimension produces a matrix of shape $(n, 2m)$:

$$\begin{bmatrix} A & B \end{bmatrix},$$

and stacking them in the third dimension produces a three-dimensional array of shape $(n, m, 2)$.

The version which takes a two-dimensional array of expressions constructs a block matrix with the given expressions as blocks. The dimensions of the blocks must be suitably compatible.

Parameters

- `dim` (`int`) – The dimension in which to stack.
- `exprs` (`Expression[]`) – A list of expressions.

- `exprs` (*Expression*[]) – A list of expressions.
- `e1` (*Expression*) – An expression.
- `e2` (*Expression*) – An expression.
- `a2` (`double`) – A scalar constant.
- `v2` (*Variable*) – A variable.
- `a1` (`double`) – A scalar constant.
- `v1` (*Variable*) – A variable.
- `a3` (`double`) – A scalar constant.
- `v3` (*Variable*) – A variable.
- `e3` (*Expression*) – An expression.

Return (*Expression*)

`Expr.sub`

```

Expression::t Expr::sub(Expression::t e1, Expression::t e2)
Expression::t Expr::sub(Expression::t e1, Variable::t v2)
Expression::t Expr::sub(Variable::t v1, Expression::t e2)
Expression::t Expr::sub(Expression::t e1, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::sub(Expression::t e1, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::sub(shared_ptr<ndarray<double,1>> a1, Expression::t e2)
Expression::t Expr::sub(shared_ptr<ndarray<double,2>> a2, Expression::t e2)
Expression::t Expr::sub(Expression::t e1, double c)
Expression::t Expr::sub(double c, Expression::t e2)
Expression::t Expr::sub(Expression::t e1, Matrix::t m)
Expression::t Expr::sub(Matrix::t m, Expression::t e2)
Expression::t Expr::sub(Expression::t e1, NDSparseArray::t n)
Expression::t Expr::sub(NDSparseArray::t n, Expression::t e2)
Expression::t Expr::sub(Variable::t v1, Variable::t v2)
Expression::t Expr::sub(Variable::t v1, shared_ptr<ndarray<double,1>> a1)
Expression::t Expr::sub(Variable::t v1, shared_ptr<ndarray<double,2>> a2)
Expression::t Expr::sub(shared_ptr<ndarray<double,1>> a1, Variable::t v2)
Expression::t Expr::sub(shared_ptr<ndarray<double,2>> a2, Variable::t v2)
Expression::t Expr::sub(Variable::t v1, double c)
Expression::t Expr::sub(double c, Variable::t v2)
Expression::t Expr::sub(Variable::t v1, Matrix::t m)
Expression::t Expr::sub(Matrix::t m, Variable::t v2)
Expression::t Expr::sub(Variable::t v1, NDSparseArray::t n)
Expression::t Expr::sub(NDSparseArray::t n, Variable::t v2)

```

Computes the difference of two expressions. The expressions must have the same shape and the result will be also an expression of that shape. The allowed combinations of arguments are the same as for *Expr.add*.

Parameters

- `e1` (*Expression*) – An expression.
- `e2` (*Expression*) – An expression.
- `v2` (*Variable*) – A variable.
- `v1` (*Variable*) – A variable.
- `a1` (`double[]`) – An array of constants.
- `a2` (`double[][]`) – An array of constants.
- `c` (`double`) – A constant.

- `m` (*Matrix*) – A Matrix object.
- `n` (*NDSparseArray*) – An NDSparseArray object.

Return (*Expression*)

`Expr.sum`

```
Expression::t Expr::sum(Expression::t expr)
Expression::t Expr::sum(Variable::t v)
Expression::t Expr::sum(Variable::t v, int d)
Expression::t Expr::sum(Variable::t v, int dfirst, int dlast)
Expression::t Expr::sum(Expression::t expr, int d)
Expression::t Expr::sum(Expression::t expr, int dfirst, int dlast)
```

Sum the elements of an expression. Without extra arguments, all elements are summed into a scalar expression of size 1.

With arguments `dfirst`, `dlast` or `d`, elements are summed along a specific dimension or a range of dimensions, resulting in an expression of reduced dimension. Note that the result of summing over a dimension of size 0 is 0.0. This means that for an expression of shape $(2,0,2)$, summing over the second dimension yields an expression of shape $(2,2)$ of zeros.

For example, if the argument is an $n \times m$ matrix then summing along the first dimension computes the $1 \times m$ vector of column sums, and summing over the second dimension computes the $n \times 1$ vector of row sums.

Parameters

- `expr` (*Expression*) – An expression object.
- `v` (*Variable*) – A variable.
- `d` (`int`) – The dimension in which to sum.
- `dfirst` (`int`) – The first dimension to sum.
- `dlast` (`int`) – The last-plus-one dimension to sum.

Return (*Expression*)

`Expr.toString`

```
string toString()
```

Create a human readable string representation of the expression.

Return (`string`)

`Expr.transpose`

```
Expression::t transpose()
```

Transpose the expression. The expression must have at most two dimensions.

Return (*Expression*)

`Expr.vstack`

```
Expression::t Expr::vstack(shared_ptr<ndarray<Expression::t,1>> exprs)
Expression::t Expr::vstack(Expression::t e1, Expression::t e2)
Expression::t Expr::vstack(Expression::t e1, Variable::t v2)
Expression::t Expr::vstack(Expression::t e1, double a2)
Expression::t Expr::vstack(Variable::t v1, Expression::t e2)
```

```

Expression::t Expr::vstack(Variable::t v1, Variable::t v2)
Expression::t Expr::vstack(Variable::t v1, double a2)
Expression::t Expr::vstack(double a1, Expression::t e2)
Expression::t Expr::vstack(double a1, Variable::t v2)
Expression::t Expr::vstack(Expression::t e1, Expression::t e2, Expression::t e3)
Expression::t Expr::vstack(Expression::t e1, Expression::t e2, Variable::t v3)
Expression::t Expr::vstack(Expression::t e1, Expression::t e2, double a3)
Expression::t Expr::vstack(Expression::t e1, Variable::t v2, Expression::t e3)
Expression::t Expr::vstack(Expression::t e1, Variable::t v2, Variable::t v3)
Expression::t Expr::vstack(Expression::t e1, Variable::t v2, double a3)
Expression::t Expr::vstack(Expression::t e1, double a2, Expression::t e3)
Expression::t Expr::vstack(Expression::t e1, double a2, Variable::t v3)
Expression::t Expr::vstack(Expression::t e1, double a2, double a3)
Expression::t Expr::vstack(Variable::t v1, Expression::t e2, Expression::t e3)
Expression::t Expr::vstack(Variable::t v1, Expression::t e2, Variable::t v3)
Expression::t Expr::vstack(Variable::t v1, Expression::t e2, double a3)
Expression::t Expr::vstack(Variable::t v1, Variable::t v2, Expression::t e3)
Expression::t Expr::vstack(Variable::t v1, Variable::t v2, Variable::t v3)
Expression::t Expr::vstack(Variable::t v1, Variable::t v2, double a3)
Expression::t Expr::vstack(Variable::t v1, double a2, Expression::t e3)
Expression::t Expr::vstack(Variable::t v1, double a2, Variable::t v3)
Expression::t Expr::vstack(Variable::t v1, double a2, double a3)
Expression::t Expr::vstack(double a1, Expression::t e2, Expression::t e3)
Expression::t Expr::vstack(double a1, Expression::t e2, Variable::t v3)
Expression::t Expr::vstack(double a1, Expression::t e2, double a3)
Expression::t Expr::vstack(double a1, Variable::t v2, Expression::t e3)
Expression::t Expr::vstack(double a1, Variable::t v2, Variable::t v3)
Expression::t Expr::vstack(double a1, Variable::t v2, double a3)
Expression::t Expr::vstack(double a1, double a2, Expression::t e3)
Expression::t Expr::vstack(double a1, double a2, Variable::t v3)
Expression::t Expr::vstack(double a1, double a2, double a3)

```

Stack a list of expressions vertically (i.e. along the first dimension). The expressions must have the same shape, except for the first dimension. The arguments may be any combination of expressions, scalar constants and variables.

For example, if y^1, y^2, y^3 are three horizontal vectors of length n (and shape $(1, n)$) then their vertical stack is the matrix

$$\begin{bmatrix} -y^1- \\ -y^2- \\ -y^3- \end{bmatrix}$$

of shape $(3, n)$.

Parameters

- `exprs` (*Expression*[]) – A list of expressions.
- `e1` (*Expression*) – An expression.
- `e2` (*Expression*) – An expression.
- `v2` (*Variable*) – A variable.
- `a2` (*double*) – A scalar constant.
- `v1` (*Variable*) – A variable.
- `a1` (*double*) – A scalar constant.
- `e3` (*Expression*) – An expression.
- `v3` (*Variable*) – A variable.
- `a3` (*double*) – A scalar constant.

Return (*Expression*)

Expr.zeros

```
Expression::t Expr::zeros(int num)
```

Create a vector of zeros as an expression.

Parameters num (int) – The size of the expression.

Return (*Expression*)

14.2.12 Class Expression

mosek::fusion::Expression

Abstract base class for all objects which can be used as linear expressions of the form $Ax + b$.

The main use of this class is to store the result of expressions created by the static methods provided by *Expr*.

Members *Expression.eval* – Evaluate the expression into simple sparse form.

Expression.getModel – Return the Model object to which the expression belongs.

Expression.getShape – Get the shape of the expression.

Expression.index – Get a single element in the expression.

Expression.pick – Pick a number of elements from the expression.

Expression.shape – Get the shape of the expression.

Expression.slice – Get a slice of the expression.

Expression.toString – Return a string representation of the expression object.

Expression.transpose – Transpose the expression.

Implemented by *Expr*

Expression.eval

```
FlatExpr::t eval()
```

Evaluate the expression into simple sparse form.

Return (*FlatExpr*)

Expression.getModel

```
Model::t getModel()
```

Return the Model object to which the expression belongs.

Return (*Model*)

Expression.getShape

```
Set::t getShape()
```

Get the shape of the expression.

Return (*Set*)

Expression.index

```
Expression::t index(int i)
Expression::t index(shared_ptr<ndarray<int,1>> indexes)
```

Get a single element in the expression.

Parameters

- `i` (`int`) – Index of the element to pick.
- `indexes` (`int[]`) – Multi-dimensional index of the element to pick.

Return (*Expression*)

Expression.pick

```
Expression::t pick(shared_ptr<ndarray<int,1>> indexes)
Expression::t pick(shared_ptr<ndarray<int,2>> indexrows)
```

Picks a number of elements from the expression and returns them as a one-dimensional expression.

Parameters

- `indexes` (`int[]`) – Indexes of the elements to pick
- `indexrows` (`int[][]`) – Indexes of the elements to pick. Each row defines a separate multi-dimensional index.

Return (*Expression*)

Expression.shape

```
Set::t shape()
```

Get the shape of the expression.

Return (*Set*)

Expression.slice

```
Expression::t slice(int first, int last)
Expression::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Get a slice of the expression.

Parameters

- `first` (`int`) – Index of the first element in the slice.
- `last` (`int`) – Index of the last element in the slice plus one.
- `firsta` (`int[]`) – Multi-dimensional index of the first element in the slice.
- `lasta` (`int[]`) – Multi-dimensional index of the element after the end of the slice.

Return (*Expression*)

Expression.toString

```
string toString()
```

Return a string representation of the expression object.

Return (`string`)

Expression.transpose

```
Expression::t transpose()
```

Transpose the expression. The expression must have at most two dimensions.

Return (*Expression*)

14.2.13 Class FlatExpr

mosek::fusion::FlatExpr

Defines a simple structure containing a sparse representation of a linear expression; basically the result of evaluating an *Expression* object.

Members *FlatExpr.size* – Get the number of non-zero elements in the expression.

FlatExpr.toString – Create a human readable string representation of the expression.

FlatExpr.size

```
int size()
```

Get the number of non-zero elements in the expression.

Return (int)

FlatExpr.toString

```
string toString()
```

Create a human readable string representation of the expression.

Return (string)

14.2.14 Class LinPSDDomain

mosek::fusion::LinPSDDomain

Represent a linear PSD domain.

14.2.15 Class LinearConstraint

mosek::fusion::LinearConstraint

A linear constraint defines a block of constraints with the same linear domain. The domain is either a product of product of one-dimensional half-spaces (linear inequalities), a fixed value vector (equalities) or the whole space (free constraints).

The *type* of a linear variable is immutable; it is either free, an inequality or an equality, but the linear expression and the right-hand side can be modified.

The class is not meant to be instantiated directly, but must be created by calling the *Model.variable* method.

Implements *ModelConstraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.
Constraint.index – Get a single element from a constraint.
Constraint.level – Get the primal solution values of the constraint.
Constraint.shape – Return the constraint's shape.
Constraint.size – Get the total number of elements in the constraint.
ModelConstraint.slice – Create a slice constraint.
ModelConstraint.toString – Create a human readable string representation of the constraint.

14.2.16 Class LinearDomain

`mosek::fusion::LinearDomain`

Represent a domain defined by linear constraints

Members *LinearDomain.integral* – Creates a domain of integral variables.

LinearDomain.sparse – Creates a domain exploiting sparsity.

LinearDomain.symmetric – Creates a symmetric domain

`LinearDomain.integral`

`LinearDomain::t integral()`

Modify a given domain restricting its elements to be integral.

Return (*LinearDomain*)

`LinearDomain.sparse`

`LinearDomain::t sparse()`

Modify a given domain exploiting sparsity, i.e only instantiating the variables that are actually used in the model.

Return (*LinearDomain*)

`LinearDomain.symmetric`

`SymmetricLinearDomain::t symmetric()`

Creates a symmetric domain

Return (*SymmetricLinearDomain*)

14.2.17 Class LinearPSDConstraint

`mosek::fusion::LinearPSDConstraint`

This class represents a semidefinite conic constraint of the form

$$Ax - b \succeq 0$$

i.e. $Ax - b$ must be positive semidefinite

Implements *ModelConstraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

LinearPSDConstraint.toString – Create a human readable string representation of the constraint.

ModelConstraint.slice – Create a slice constraint.

`LinearPSDConstraint.toString`

```
string toString()
```

Create a human readable string representation of the constraint.

Return (string)

14.2.18 Class LinearPSDVariable

`mosek::fusion::LinearPSDVariable`

This class represents a positive semidefinite variable.

Implements *ModelVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

LinearPSDVariable.toString – Create a string representation of the variable.

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

`LinearPSDVariable.toString`

`string toString()`

Create a string representation of the variable.

Return (string)

14.2.19 Class LinearVariable

`mosek::fusion::LinearVariable`

A linear variable defines a block of variables with the same linear domain. The domain is either a product of product of one-dimensional half-spaces (linear inequalities), a fixed value vector (equalities) or the whole space (free variables).

The *type* of a linear variable is immutable; it is either free, an inequality or an equality.

The class is not meant to be instantiated directly, but must be created by calling the *Model.variable* method.

Implements *ModelVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

14.2.20 Class Matrix

`mosek::fusion::Matrix`

Base class for all matrix objects. It can be used to create and manipulate matrices of constant coefficients both in dense and sparse format. To operate with matrices containing variables and linear expressions use the classes *Expr* and *Variable*.

Members *Matrix.get* – Get a single entry.

Matrix.getDataAsArray – Return a dense array of values.

Matrix.getDataAsTriplets – Return the matrix data in sparse triplet format.

Matrix.isSparse – Returns true if the matrix is sparse.

Matrix.numColumns – Returns the number of columns in the matrix.

Matrix.numNonzeros – Returns the number of non-zeros in the matrix.

Matrix.numRows – Returns the number of rows in the matrix.

Matrix.toString – Get a string representation of the matrix.

Matrix.transpose – Transpose the matrix.

Static members *Matrix.antiDiag* – Create a sparse square matrix with a given vector as anti-diagonal.

Matrix.dense – Create a dense matrix from the given data.

Matrix.diag – Create a sparse square matrix with a given vector as diagonal.

Matrix.eye – Create the identity matrix.

Matrix.ones – Create a matrix filled with all ones.

Matrix.sparse – Create a sparse matrix from the given data.

`Matrix.antiDiag`

```
Matrix::t Matrix::antiDiag(shared_ptr<ndarray<double,1>> d)
Matrix::t Matrix::antiDiag(shared_ptr<ndarray<double,1>> d, int k)
Matrix::t Matrix::antiDiag(int n, double val)
Matrix::t Matrix::antiDiag(int n, double val, int k)
```

Create a sparse square matrix with a given vector as anti-diagonal.

Parameters

- `d (double[])` – The anti-diagonal vector.
- `k (int)` – The anti-diagonal index. $k = 0$ is the default and means the main anti-diagonal. $k > 0$ means above, and $k < 0$ means below the main anti-diagonal.
- `n (int)` – The dimension of the matrix.
- `val (double)` – Use this value for all anti-diagonal elements.

Return (*Matrix*)

`Matrix.dense`

```
Matrix::t Matrix::dense(shared_ptr<ndarray<double,2>> data)
Matrix::t Matrix::dense(int dimi, int dimj, shared_ptr<ndarray<double,1>> data)
Matrix::t Matrix::dense(int dimi, int dimj, double value)
Matrix::t Matrix::dense(Matrix::t other)
```

Create a dense matrix from the given data.

Parameters

- `data (double[[[[]]])` – A one- or two-dimensional array of matrix coefficients.
- `data (double[[[]]])` – A one- or two-dimensional array of matrix coefficients.
- `dimi (int)` – Number of rows.
- `dimj (int)` – Number of columns.
- `value (double)` – Use this value for all elements.
- `other (Matrix)` – Create a dense matrix from another matrix.

Return (*Matrix*)`Matrix.diag`

```
Matrix::t Matrix::diag(shared_ptr<ndarray<double,1>> d)
Matrix::t Matrix::diag(shared_ptr<ndarray<double,1>> d, int k)
Matrix::t Matrix::diag(int n, double val)
Matrix::t Matrix::diag(int n, double val, int k)
Matrix::t Matrix::diag(shared_ptr<ndarray<Matrix::t,1>> md)
Matrix::t Matrix::diag(int num, Matrix::t mv)
```

Create a sparse square matrix with a given vector as diagonal.

Parameters

- `d (double[[[]]])` – The diagonal vector.
- `k (int)` – The diagonal index. $k = 0$ is the default and means the main diagonal. $k > 0$ means above, and $k < 0$ means below the main diagonal.
- `n (int)` – The dimension of the matrix.
- `val (double)` – Use this value for all diagonal elements.
- `md (Matrix[[[]]])` – A list of square matrices that are used to create a block-diagonal square matrix.
- `num (int)` – Number of times to repeat the `mv` matrix.
- `mv (Matrix)` – A matrix to be repeated in all blocks of a block-diagonal square matrix.

Return (*Matrix*)`Matrix.eye`

```
Matrix::t Matrix::eye(int n)
```

Construct the identity matrix of size n .**Parameters** `n (int)` – The dimension of the matrix.**Return** (*Matrix*)`Matrix.get`

```
double get(int i, int j)
```

Get a single entry.

Parameters

- `i (int)` – Row index.

- `j` (`int`) – Column index.

Return (`double`)

`Matrix.getDataAsArray`

```
shared_ptr<ndarray<double,1>> getDataAsArray()
```

Return the matrix elements as a dense array in row-major format.

Return (`double[]`)

`Matrix.getDataAsTriplets`

```
void getDataAsTriplets(shared_ptr<ndarray<int,1>> subi, shared_ptr<ndarray<int,1>> subj,
↳ shared_ptr<ndarray<double,1>> val)
```

Return the matrix data in sparse triplet format. Data is copied to the arrays `subi`, `subj` and `val` which must be pre-allocated to hold at least the number of non-zeros in the matrix.

The data returned must be ordered with `subi` as primary key and `subj` as secondary key.

Parameters

- `subi` (`int[]`) – Row subscripts are returned in this array.
- `subj` (`int[]`) – Column subscripts are returned in this array.
- `val` (`double[]`) – Coefficient values are returned in this array.

`Matrix.isSparse`

```
bool isSparse()
```

Returns true if the matrix is sparse.

Return (`bool`)

`Matrix.numColumns`

```
int numColumns()
```

Returns the number of columns in the matrix.

Return (`int`)

`Matrix.numNonzeros`

```
long long numNonzeros()
```

Returns the number of non-zeros in the matrix.

Return (`long long`)

`Matrix.numRows`

```
int numRows()
```

Returns the number of rows in the matrix.

Return (`int`)

Matrix.ones

```
Matrix::t Matrix::ones(int n, int m)
```

Construct a matrix filled with ones.

Parameters

- `n` (`int`) – Number of rows.
- `m` (`int`) – Number of columns.

Return (*Matrix*)

Matrix.sparse

```
Matrix::t Matrix::sparse(int nrow, int ncol, shared_ptr<ndarray<int,1>> subi, shared_ptr<
↳ ndarray<int,1>> subj, shared_ptr<ndarray<double,1>> val)
Matrix::t Matrix::sparse(shared_ptr<ndarray<int,1>> subi, shared_ptr<ndarray<int,1>> subj,
↳ shared_ptr<ndarray<double,1>> val)
Matrix::t Matrix::sparse(shared_ptr<ndarray<int,1>> subi, shared_ptr<ndarray<int,1>> subj,
↳ double val)
Matrix::t Matrix::sparse(int nrow, int ncol, shared_ptr<ndarray<int,1>> subi, shared_ptr
↳ ndarray<int,1>> subj, double val)
Matrix::t Matrix::sparse(int nrow, int ncol)
Matrix::t Matrix::sparse(shared_ptr<ndarray<double,2>> data)
Matrix::t Matrix::sparse(shared_ptr<ndarray<Matrix::t,2>> blocks)
Matrix::t Matrix::sparse(Matrix::t mx)
```

Create a sparse matrix from the given data.

Parameters

- `nrow` (`int`) – Number of rows.
- `ncol` (`int`) – Number of columns.
- `subi` (`int[]`) – Row subscripts of non-zero elements.
- `subj` (`int[]`) – Column subscripts of non-zero elements.
- `val` (`double[]`) – Coefficients of non-zero elements.
- `val` (`double`) – Coefficients of non-zero elements.
- `data` (`double[][]`) – Dense data array.
- `blocks` (*Matrix* `[][]`) – The matrix data in block format. All elements in a row must have the same height, and all elements in a column must have the same width. Entries that are NULL will be interpreted as a block of zeros whose height and width are deduced from the other elements in the same row and column. Any row that contains only NULL entries will have height 0, and any column that contains only NULL entries will have width 0.
- `mx` (*Matrix*) – A *Matrix* object.

Return (*Matrix*)

Matrix.toString

```
string toString()
```

Get a string representation of the matrix.

Return (`string`)

`Matrix.transpose`

<code>Matrix::t transpose()</code>

Transpose the matrix.

Return (*Matrix*)

14.2.21 Class Model

`mosek::fusion::Model`

The object containing all data related to a single optimization model.

Implements `BaseModel`

Members *Model.acceptedSolutionStatus* – Set the accepted solution status.

Model.breakSolver – Request that the solver terminates as soon as possible.

Model.clone – Return a copy of the model.

Model.constraint – Create a new constraint in the model.

Model.dispose – Destroy the Model object

Model.dualObjValue – Get the dual objective value in the current solution.

Model.flushSolutions – If any solution values have been provided, flush those values to the underlying task.

Model.getAcceptedSolutionStatus – Get the accepted solution status.

Model.getConstraint – Get the constraint matching the given name or linear index.

Model.getDualSolutionStatus – Return the status of the dual solution.

Model.getName – Return the model name, or an empty string if it has not been set.

Model.getPrimalSolutionStatus – Return the status of the primal solution.

Model.getProblemStatus – Return the problem status.

Model.getSolverDoubleInfo – Fetch a solution information item from the solver

Model.getSolverIntInfo – Fetch a solution information item from the solver

Model.getSolverLIntInfo – Fetch a solution information item from the solver

Model.getTask – Return the underlying MOSEK task object.

Model.getVariable – Get the variable matching the given name or linear index.

Model.hasConstraint – Check whether the model contains a constraint with a given name.

Model.hasVariable – Check whether the model contains a variable with a given name.

Model.numConstraints – Return the number of constraints.

Model.numVariables – Return the number of variables.

Model.objective – Replace the objective expression.

Model.primalObjValue – Get the primal objective value in the current solution.

Model.selectedSolution – Chooses a solution.

Model.setCallbackHandler – Attach a progress callback handler.

Model.setDataCallbackHandler – Attach a data callback handler.

Model.setLogHandler – Attach a log handler.

Model.setSolverParam – Set a solver parameter

Model.solve – Attempt to optimize the model.

Model.variable – Create a new variable in the model.

Model.writeTask – Dump the current solver task to a file.

Static members *Model.putLicenseCode* – Set the license code in the global environment.

Model.putLicensePath – Set the license path in the global environment.

Model.putLicenseWait – Set the license wait flag in the global environment.

Model.acceptedSolutionStatus

```
void acceptedSolutionStatus(AccSolutionStatus what)
```

Set the accepted solution status. This defines which solution status values are considered as *acceptable* when fetching a solution. Requesting a solution value for a variable or constraint when the status does not match at least the accepted value will cause an error.

By default the accepted solution status is *AccSolutionStatus.NearOptimal*. It is necessary to change the accepted status to access sub-optimal solutions and infeasibility certificates.

The methods *Model.getPrimalSolutionStatus* and *Model.getDualSolutionStatus* can be used to get the *actual* status of the solutions.

Parameters *what* (*AccSolutionStatus*) – The new accepted solution status.

Model.breakSolver

```
void breakSolver()
```

Request that the solver terminates as soon as possible. This must be called from another thread than the one in which *solve()* was called, or from a callback function.

The method does not stop the solver directly, rather it sets a flag that the solver checks occasionally, indicating it should terminate.

Model.clone

```
Model::t clone()
```

Return a copy of the model.

Return (*Model*)

Model.constraint

```
Constraint::t constraint(string name, Expression::t expr, PSDDomain::t psddom)
Constraint::t constraint(Expression::t expr, PSDDomain::t psddom)
Constraint::t constraint(string name, Expression::t expr, LinPSDDomain::t lpsddom)
Constraint::t constraint(Expression::t expr, LinPSDDomain::t lpsddom)
Constraint::t constraint(string name, Set::t shape, Expression::t expr, LinearDomain::t ldom)
Constraint::t constraint(Set::t shape, Expression::t expr, LinearDomain::t ldom)
Constraint::t constraint(string name, Expression::t expr, LinearDomain::t ldom)
Constraint::t constraint(Expression::t expr, LinearDomain::t ldom)
Constraint::t constraint(string name, Set::t shape, Expression::t expr, RangeDomain::t rdom)
Constraint::t constraint(Set::t shape, Expression::t expr, RangeDomain::t rdom)
```

```

Constraint::t constraint(Set::t shape, Expression::t expr, RangeDomain::t rdom)
Constraint::t constraint(string name, Expression::t expr, RangeDomain::t rdom)
Constraint::t constraint(Expression::t expr, RangeDomain::t rdom)
Constraint::t constraint(string name, Set::t shape, Expression::t expr, QConeDomain::t
↳ qdom)
Constraint::t constraint(Set::t shape, Expression::t expr, QConeDomain::t qdom)
Constraint::t constraint(string name, Expression::t expr, QConeDomain::t qdom)
Constraint::t constraint(Expression::t expr, QConeDomain::t qdom)
Constraint::t constraint(string name, Variable::t v, PSDDomain::t psddom)
Constraint::t constraint(Variable::t v, PSDDomain::t psddom)
Constraint::t constraint(string name, Variable::t v, LinPSDDomain::t lpsddom)
Constraint::t constraint(Variable::t v, LinPSDDomain::t lpsddom)
Constraint::t constraint(string name, Set::t shape, Variable::t v, LinearDomain::t ldom)
Constraint::t constraint(Set::t shape, Variable::t v, LinearDomain::t ldom)
Constraint::t constraint(string name, Variable::t v, LinearDomain::t ldom)
Constraint::t constraint(Variable::t v, LinearDomain::t ldom)
Constraint::t constraint(string name, Set::t shape, Variable::t v, RangeDomain::t rdom)
Constraint::t constraint(Set::t shape, Variable::t v, RangeDomain::t rdom)
Constraint::t constraint(string name, Variable::t v, RangeDomain::t rdom)
Constraint::t constraint(Variable::t v, RangeDomain::t rdom)
Constraint::t constraint(string name, Set::t shape, Variable::t v, QConeDomain::t qdom)
Constraint::t constraint(Set::t shape, Variable::t v, QConeDomain::t qdom)
Constraint::t constraint(string name, Variable::t v, QConeDomain::t qdom)
Constraint::t constraint(Variable::t v, QConeDomain::t qdom)

```

Adds a new constraint to the model. A constraint is always a statement that *an expression or variable* belongs to *a domain*. Constraints can have optional names.

Typical domains used for defining constraints include:

- *Domain.lessThan*, *Domain.greaterThan*, *Domain.inRange* — puts linear bounds $E \leq u$, $l \leq E$ or $l \leq E \leq u$ on an expresion E .
- *Domain.inQCone*, *Domain.inRotatedQCone* — constrains a vector or matrix expression E to a second-order cone.
- *Domain.inPSDCone* — constrains a square matrix expression E to be positive semidefinite.

Parameters

- **name** (*string*) – Name of the constraint. This must be unique among all constraints in the model. The value NULL is allowed instead of a unique name.
- **expr** (*Expression*) – An expression.
- **psddom** (*PSDDomain*) – A positive semidefinite domain.
- **lpsddom** (*LinPSDDomain*) – A linear positive semidefinite domain.
- **shape** (*Set*) – Defines the shape of the constraint. If this is NULL, the shape will be derived from the shape of the expression or variable.
- **ldom** (*LinearDomain*) – A linear domain.
- **rdom** (*RangeDomain*) – A ranged domain.
- **qdom** (*QConeDomain*) – A domain in a second order cone.
- **v** (*Variable*) – A variable used as an expression.

Return (*Constraint*)

`Model.dispose`

```
void dispose()
```

Destroy the Model object. This removes all references to other objects from the Model.

This helps garbage collection by removing cyclic references, and in some cases it is necessary to ensure that the garbage collector can collect the Model object and associated objects.

Model.dualObjValue

```
double dualObjValue()
```

Get the dual objective value in the current solution.

Return (double)

Model.flushSolutions

```
void flushSolutions()
```

If any solution values have been provided, flush those values to the underlying task.

Model.getAcceptedSolutionStatus

```
AccSolutionStatus getAcceptedSolutionStatus()
```

Get the accepted solution status.

Return (*AccSolutionStatus*)

Model.getConstraint

```
Constraint::t getConstraint(string name)
Constraint::t getConstraint(int index)
```

Get the constraint matching the given name or linear index. Constraints are assigned indices in the order they are added to the model.

Parameters

- **name** (string) – The constraint's name.
- **index** (int) – The constraint's linear index.

Return (*Constraint*)

Model.getDualSolutionStatus

```
SolutionStatus getDualSolutionStatus(SolutionType which)
SolutionStatus getDualSolutionStatus()
```

Return the status of the dual solution. If no solution type is given the solution set with *Model.selectedSolution* is checked. It is recommended to check the problem and solution status before accessing the solution values.

Parameters **which** (*SolutionType*) – The type of the solution for which status is requested.

Return (*SolutionStatus*)

Model.getName

```
string getName()
```

Return the model name, or an empty string if it has not been set.

Return (string)

`Model.getPrimalSolutionStatus`

```
SolutionStatus getPrimalSolutionStatus(SolutionType which)
SolutionStatus getPrimalSolutionStatus()
```

Return the status of the primal solution. If no solution type is given the solution set with *Model.selectedSolution* is checked. It is recommended to check the problem and solution status before accessing the solution values.

Parameters which (*SolutionType*) – The type of the solution for which status is requested.

Return (*SolutionStatus*)

`Model.getProblemStatus`

```
ProblemStatus getProblemStatus(SolutionType which)
```

Return the problem status. It is recommended to check the problem and solution status before accessing the solution values.

Parameters which (*SolutionType*) – The type of the solution.

Return (*ProblemStatus*)

`Model.getSolverDoubleInfo`

```
double getSolverDoubleInfo(string name)
```

This method returns the value for the specified double solver information item. The information items become available during and after the solver execution. A runtime exception is thrown if a non-existing information item is requested. The double information items are listed in Section *Double information items*.

Parameters name (string) – A string name of the information item.

Return (double)

`Model.getSolverIntInfo`

```
int getSolverIntInfo(string name)
```

This method returns the value for the specified integer solver information item. The information items become available during and after the solver execution. A runtime exception is thrown if a non-existing information item is requested. The integer information items are listed in Section *Integer information items*.

Parameters name (string) – A string name of the information item.

Return (int)

`Model.getSolverLIntInfo`

```
long long getSolverLIntInfo(string name)
```

This method returns the value for the specified long solver information item. The information items become available during and after the solver execution. A runtime exception is thrown if a

non-existing information item is requested. The long integer information items are listed in Section [Long integer information items](#).

Parameters `name (string)` – A string name of the information item.

Return `(long long)`

`Model.getTask`

```
mosek.Task getTask()
```

Returns the underlying **MOSEK** Task object. Note that the returned object is the actual underlying object, not a copy. This means if the returned object is modified by the user, the *Model* object may become invalid. Accessing the task object should never be necessary, except maybe for advanced debugging. For details on the Task object see the Optimizer API documentation.

Return `(Task)`

`Model.getVariable`

```
Variable::t getVariable(string name)
Variable::t getVariable(int index)
```

Get the variable matching the given name or linear index. Variables are assigned indices in the order they are added to the model.

Parameters

- `name (string)` – The variable's name.
- `index (int)` – The variable's linear index.

Return `(Variable)`

`Model.hasConstraint`

```
bool hasConstraint(string name)
```

Check whether the model contains a constraint with a given name.

Parameters `name (string)` – The constraint name.

Return `(bool)`

`Model.hasVariable`

```
bool hasVariable(string name)
```

Check whether the model contains a variable with a given name.

Parameters `name (string)` – The variable name.

Return `(bool)`

`Model.numConstraints`

```
long long numConstraints()
```

Return the number of constraints.

Return `(long long)`

Model.numVariables

```
long long numVariables()
```

Return the number of variables.

Return (long long)

Model.objective

```
void objective(string name, ObjectiveSense sense, Expression::t expr)
void objective(string name, ObjectiveSense sense, Variable::t v)
void objective(string name, ObjectiveSense sense, double c)
void objective(string name, double c)
void objective(ObjectiveSense sense, Expression::t expr)
void objective(ObjectiveSense sense, Variable::t v)
void objective(ObjectiveSense sense, double c)
void objective(double c)
```

Replace the objective expression. This method must be called at least once before the first *Model.solve*.

Parameters

- **name** (string) – Name of the objective. This may be any string, and it has no function except when writing the problem to an external file format.
- **sense** (*ObjectiveSense*) – The objective sense. Defines whether the objective must be minimized or maximized.
- **expr** (*Expression*) – The objective expression. This must be an expression that evaluates to a scalar.
- **v** (*Variable*) – The objective variable. This must be a scalar variable.
- **c** (double) – A constant scalar.

Model.primalObjValue

```
double primalObjValue()
```

Get the primal objective value in the current solution.

Return (double)

Model.putlicensecode

```
void Model::putlicensecode(shared_ptr<ndarray<int,1>> code)
```

Set the license code in the global environment.

Parameters code (int[])

Model.putlicensepath

```
void Model::putlicensepath(string licfile)
```

Set the license path in the global environment.

Parameters licfile (string)

Model.putlicensewait

```
void Model::putlicensewait(bool wait)
```

Set the license wait flag in the global environment. If set, **MOSEK** will wait until a license becomes available.

Parameters wait (bool)

Model.selectedSolution

```
void selectedSolution(SolutionType soltype)
```

Chooses a solution. The values of variables and constraints will be read from the chosen solution. The default is to consider all solution types in the order of *SolutionType.Default*.

Parameters soltype (*SolutionType*)

Model.setCallbackHandler

```
void setCallbackHandler(System.CallbackHandler h)
```

Attach a progress callback handler. During optimization this handler will be called, providing a code with the current state of the solver. Passing NULL detaches the current handler. See Section *Progress and data callback* for details and examples and the Optimizer API for information about callback codes.

The progress callback handler is a function of type `std::function<int(MSKcallbackcodee)>`.

Parameters h (CallbackHandler) – The callback handler or NULL.

Model.setDataCallbackHandler

```
void setDataCallbackHandler(System.DataCallbackHandler h)
```

Attach a data callback handler. During optimization this handler will be called, providing various information about the current state of the solution and solver. Passing NULL detaches the current handler. See Section *Progress and data callback* for details and examples and the Optimizer API for information about callback codes.

The data callback handler is a function of type `std::function<bool(MSKcallbackcodee, const double *, const int32_t *, const int64_t *)>`.

Parameters h (DataCallbackHandler) – The callback handler or NULL.

Model.setLogHandler

```
void setLogHandler(System.StreamWriter h)
```

Attach a log handler. The solver log information will be sent to the stream handler. Passing NULL detaches the current handler.

The log handler is a function of type `std::function<void(const std::string &)>`, for example

```
M->setLogHandler([](const std::string & msg) { std::cout << msg << std::flush; } );
```

Parameters h (StreamWriter) – The log handler object or NULL.

Model.setSolverParam

```
void setSolverParam(string name, string strval)
void setSolverParam(string name, int intval)
void setSolverParam(string name, double floatval)
```

Set a solver parameter. Solver parameter values can be either symbolic values, integers or doubles, depending on the parameter. The value is automatically converted to a suitable type whenever possible. If this fails, an exception will be thrown. For example, if the parameter accepts a double value and is given a string, the string will be parsed to produce a double.

See Section *Parameters (alphabetical list sorted by type)* for a listing of all parameter settings.

Parameters

- **name** (string) – Name of the parameter to set
- **strval** (string) – A string value to assign to the parameter.
- **intval** (int) – An integer value to assign to the parameter.
- **floatval** (double) – A floating point value to assign to the parameter.

`Model.solve`

```
void solve()
```

This calls the **MOSEK** solver to solve the problem defined in the model.

If no error occurs, on exit a solution status will be defined for the primal and the dual solutions. These can be obtained with `Model.getPrimalSolutionStatus` and `Model.getDualSolutionStatus`. Depending on the solution status, various values may be defined:

- If the model is primal-dual feasible, or nearly so, and the solver found a solution, the solution values can be accessed through the *Variable* and *Constraint* objects in the model. For integer problems only the primal solution is defined, while for continuous problems both primal and dual solutions are available.
- If the model is primal or dual infeasible, *only* the primal *or* the dual solution is defined, depending on the solution status. The available solution contains a certificate of infeasibility.
- If the status is unknown the solver ran into problems and did not find anything useful. In this case the solution values may be garbage.

The solution can be obtained with `Model.primalObjValue` and `Variable.level` and their dual analogues.

By default, trying to fetch a non-optimal solution using `Variable.level` or `Variable.dual` will cause an exception. To fetch infeasibility certificates or other less optimal solutions it is necessary to change the accepted solution flag with `Model.acceptedSolutionStatus`.

`Model.variable`

```
Variable::t variable(string name)
Variable::t variable(string name, int size)
Variable::t variable(string name, shared_ptr<ndarray<int,1>> sizea)
Variable::t variable(string name, int size, LinearDomain::t ldom)
Variable::t variable(string name, int size, RangeDomain::t rdom)
Variable::t variable(string name, int size, QConeDomain::t qdom)
Variable::t variable(string name, Set::t shp, LinearDomain::t ldom)
Variable::t variable(string name, Set::t shp, RangeDomain::t rdom)
Variable::t variable(string name, Set::t shp, QConeDomain::t qdom)
Variable::t variable(string name, shared_ptr<ndarray<int,1>> sizea, LinearDomain::t ldom)
Variable::t variable(string name, shared_ptr<ndarray<int,1>> sizea, RangeDomain::t rdom)
Variable::t variable(string name, LinearDomain::t ldom)
Variable::t variable(string name, RangeDomain::t rdom)
```

```

Variable::t variable(string name, QConeDomain::t qdom)
Variable::t variable()
Variable::t variable(int size)
Variable::t variable(shared_ptr<ndarray<int,1>> sizea)
Variable::t variable(int size, LinearDomain::t ldom)
Variable::t variable(int size, RangeDomain::t rdom)
Variable::t variable(int size, QConeDomain::t qdom)
Variable::t variable(Set::t shp, LinearDomain::t ldom)
Variable::t variable(Set::t shp, RangeDomain::t rdom)
Variable::t variable(Set::t shp, QConeDomain::t qdom)
Variable::t variable(shared_ptr<ndarray<int,1>> sizea, LinearDomain::t ldom)
Variable::t variable(shared_ptr<ndarray<int,1>> sizea, RangeDomain::t rdom)
Variable::t variable(LinearDomain::t ldom)
Variable::t variable(RangeDomain::t rdom)
Variable::t variable(QConeDomain::t qdom)
SymmetricVariable::t variable(string name, int size, SymmetricLinearDomain::t symdom)
SymmetricVariable::t variable(int size, SymmetricLinearDomain::t symdom)
Variable::t variable(string name, shared_ptr<ndarray<int,1>> sizea, PSDDomain::t psddom)
Variable::t variable(string name, Set::t shp, PSDDomain::t psddom)
Variable::t variable(string name, int n, PSDDomain::t psddom)
Variable::t variable(string name, int n, int m, PSDDomain::t psddom)
Variable::t variable(string name, PSDDomain::t psddom)
Variable::t variable(int n, PSDDomain::t psddom)
Variable::t variable(int n, int m, PSDDomain::t psddom)
Variable::t variable(PSDDomain::t psddom)
Variable::t variable(string name, shared_ptr<ndarray<int,1>> sizea, LinPSDDomain::t lpsddom)
Variable::t variable(string name, Set::t shp, LinPSDDomain::t lpsddom)
Variable::t variable(string name, int n, LinPSDDomain::t lpsddom)
Variable::t variable(string name, int n, int m, LinPSDDomain::t lpsddom)
Variable::t variable(string name, LinPSDDomain::t lpsddom)
Variable::t variable(int n, LinPSDDomain::t lpsddom)
Variable::t variable(int n, int m, LinPSDDomain::t lpsddom)
Variable::t variable(LinPSDDomain::t lpsddom)

```

Create a new variable in the model. All variables must be created using this method. The many versions of the method accept a name (optional), the shape of the variable and its domain. The domain must be suitable for the given variable shape. If the domain is not provided, it is assumed that the variable is unbounded. If the dimension is not provided the variable is a single scalar variable.

Typical domains used for creating variables include:

- *Domain.lessThan*, *Domain.greaterThan*, *Domain.inRange* — creates a variable x with bounds $x \leq u$, $l \leq x$ or $l \leq x \leq u$.
- *Domain.inPSDCone* — creates a symmetric positive definite variable of dimension n .

Parameters

- **name** (string) – Name of the variable. This must be unique among all variables in the model. The value NULL is allowed instead of a unique name.
- **size** (int) – Size of the variable. The variable becomes a one-dimensional vector of the given size.
- **sizea** (int[]) – Size of the variable. The variable becomes a multi-dimensional vector of the given size.
- **ldom** (*LinearDomain*) – A linear domain for the variable.
- **rdom** (*RangeDomain*) – A ranged domain for the variable.
- **qdom** (*QConeDomain*) – A quadratic domain for the variable.

- `shp` (*Set*) – Defines the shape of the variable.
- `symdom` (*SymmetricLinearDomain*)
- `psddom` (*PSDDomain*) – A semidefinite domain for the variable.
- `n` (`int`) – Dimension of the semidefinite variable.
- `m` (`int`) – Number of semidefinite variables.
- `lpsddom` (*LinPSDDomain*) – A linear semidefinite domain for the variable.

Return

- (*Variable*)
- (*SymmetricVariable*)

`Model.writeTask`

```
void writeTask(string filename)
```

Dump the current solver task to a file. The file extension determines the file format, see Section *Supported File Formats* for details. The file can be read with the command line **MOSEK** or with the Optimizer API for debugging purposes.

Parameters `filename` (`string`) – Name of the output file.

14.2.22 Class ModelConstraint

`mosek::fusion::ModelConstraint`

Base class for all constraints that directly corresponds to a block of constraints in the underlying task, i.e. all objects created from *Model.constraint*.

Implements *Constraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

ModelConstraint.slice – Create a slice constraint.

ModelConstraint.toString – Create a human readable string representation of the constraint.

Implemented by *PSDConstraint*, *ConicConstraint*, *LinearConstraint*, *RangedConstraint*, *LinearPSDConstraint*

`ModelConstraint.slice`

```
Constraint::t slice(int first, int last)
Constraint::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Create a slice constraint.

Parameters

- `first (int)` – Index of the first element in the slice.
- `last (int)` – Index of the first element after the end of the slice.
- `firsta (int[])` – The indexes of first elements in the slice along each dimension.
- `lasta (int[])` – The indexes of first elements after the end of the slice along each dimension.

Return (*Constraint*)`ModelConstraint.toString`

`string toString()`

Create a human readable string representation of the constraint.

Return (`string`)

14.2.23 Class `ModelVariable`

`mosek::fusion::ModelVariable`

Base class for all variables that directly corresponds to a block of variables in the underlying task, i.e. all objects created from *Model.variable*.

Implements *BaseVariable***Members** *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.*BaseVariable.asExpr* – Create an expression corresponding to the variable object.*BaseVariable.diag* – Return the diagonal of a square variable matrix.*BaseVariable.dual* – Get the dual solution value of the variable.*BaseVariable.getModel* – Return the model to which the variable belongs.*BaseVariable.getShape* – Return the shape of the variable.*BaseVariable.index* – Return a variable slice of size 1 corresponding to a single element in the variable object..*BaseVariable.level* – Get the primal solution value of the variable.*BaseVariable.makeContinuous* – Drop integrality constraints on the variable, if any.*BaseVariable.makeInteger* – Apply integrality constraints on the variable.*BaseVariable.pick* – Create a slice variable by picking a list of indexes from this variable.*BaseVariable.setLevel* – Input solution values for this variable*BaseVariable.shape* – Return the shape of the variable.*BaseVariable.size* – Get the number of elements in the variable.*BaseVariable.toString* – Create a string representation of the variable.*BaseVariable.transpose* – Transpose a vector or matrix variable*ModelVariable.slice* – Create a slice variable by picking a range of indexes for each variable dimension**Implemented by** *LinearPSDVariable*, *SymRangedVariable*, *LinearVariable*, *SymLinearVariable*, *RangedVariable*, *PSDVariable*, *ConicVariable*

ModelVariable.slice

```
Variable::t slice(int first, int last)
Variable::t slice(shared_ptr<ndarray<int,1>> first, shared_ptr<ndarray<int,1>> last)
```

Create a slice variable by picking a range of indexes for each variable dimension

Parameters

- `first (int)` – The index of the first element(s) of the slice.
- `first (int[])` – The index of the first element(s) of the slice.
- `last (int)` – The index after the last element of the slice.
- `last (int[])`

Return (*Variable*)

14.2.24 Class NDSparseArray

mosek::fusion::NDSparseArray

Representation of a sparse n-dimensional array.

Static members *NDSparseArray.make* – Create a sparse n-dimensional matrix (tensor).

NDSparseArray.make

```
NDSparseArray::t NDSparseArray::make(shared_ptr<ndarray<int,1>> dims, shared_ptr<ndarray
↪<int,2>> sub, shared_ptr<ndarray<double,1>> cof)
NDSparseArray::t NDSparseArray::make(shared_ptr<ndarray<int,1>> dims, shared_ptr<ndarray
↪<long long,1>> inst, shared_ptr<ndarray<double,1>> cof)
NDSparseArray::t NDSparseArray::make(Matrix::t m)
```

Create a sparse n-dimensional matrix (tensor).

Parameters

- `dims (int[])` – Dimensions.
- `sub (int[][])` – Positions of nonzeros. Array where each row is an n -dimensional index.
- `cof (double[])` – Values of nonzero elements. Array of coefficients corresponding to subscripts.
- `inst (long long[])` – Positions of nonzeros using linear indexes into the array.
- `m (Matrix)` – An initializing matrix.

Return (*NDSparseArray*)

14.2.25 Class PSDConstraint

mosek::fusion::PSDConstraint

This class represents a semidefinite conic constraint of the form

$$Ax - b \succeq 0$$

i.e. $Ax - b$ must be positive semidefinite

Implements *ModelConstraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

ModelConstraint.slice – Create a slice constraint.

PSDConstraint.toString – Create a human readable string representation of the constraint.

`PSDConstraint.toString`

```
string toString()
```

Create a human readable string representation of the constraint.

Return (string)

14.2.26 Class PSDDomain

`mosek::fusion::PSDDomain`

Represent the domain of PSD matrices.

14.2.27 Class PSDVariable

`mosek::fusion::PSDVariable`

This class represents a positive semidefinite variable.

Implements *ModelVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

PSDVariable.toString – Create a string representation of the variable.

PSDVariable.toString

```
string toString()
```

Create a string representation of the variable.

Return (string)

14.2.28 Class PickVariable

mosek::fusion::PickVariable

Represents an set of variable entries

Implements *BaseVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

PickVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

PickVariable.slice

```
Variable::t slice(int first, int last)
Variable::t slice(shared_ptr<ndarray<int,1>> first, shared_ptr<ndarray<int,1>> last)
```

Create a slice variable by picking a range of indexes for each variable dimension

Parameters

- `first (int)` – The index of the first element(s) of the slice.
- `first (int[])` – The index of the first element(s) of the slice.
- `last (int)` – The index after the last element of the slice.
- `last (int[])`

Return (*Variable*)

14.2.29 Class QConeDomain

`mosek::fusion::QConeDomain`

A domain representing the Lorentz cone.

Members *QConeDomain.axis* – Set the dimension along which the cones are created.

QConeDomain.GetAxis – Get the dimension along which the cones are created.

QConeDomain.integral – Creates a domain of integral variables.

`QConeDomain.axis`

```
QConeDomain::t axis(int a)
```

Set the dimension along which the cones are created.

Parameters `a (int)`

Return (*QConeDomain*)

`QConeDomain.GetAxis`

```
int getAxis()
```

Get the dimension along which the cones are created.

Return (`int`)

`QConeDomain.integral`

```
QConeDomain::t integral()
```

Modify a given domain restricting its elements to be integral.

Return (*QConeDomain*)

14.2.30 Class RangeDomain

`mosek::fusion::RangeDomain`

The *RangeDomain* object is never instantiated directly: Instead use the relevant methods in *Domain*.

Members *RangeDomain.integral* – Creates a domain of integral variables.

RangeDomain.sparse – Creates a domain exploiting sparsity.

RangeDomain.symmetric – Creates a symmetric domain.

Implemented by *SymmetricRangeDomain*

RangeDomain.integral

```
RangeDomain::t integral()
```

Modify a given domain restricting its elements to be integral.

Return (*RangeDomain*)

RangeDomain.sparse

```
RangeDomain::t sparse()
```

Modify a given domain exploiting sparsity, i.e only instantiating the variables that are actually used in the model.

Return (*RangeDomain*)

RangeDomain.symmetric

```
SymmetricRangeDomain::t symmetric()
```

Creates a symmetric domain.

Return (*SymmetricRangeDomain*)

14.2.31 Class RangedConstraint

mosek::fusion::RangedConstraint

Defines a ranged constraint.

Since this actually defines one constraint with two inequalities, there will be two dual values (slc and suc) corresponding to the lower and upper bounds. When asked for the dual solution, this constraint will return (y=slc-suc), but in some cases this is not enough (the individual dual constraints may be required for a certificate of infeasibility). The methods *RangedConstraint.lowerBoundCon* and *RangedConstraint.upperBoundCon* returns Variable objects that interface to the lower and upper bounds respectively.

Implements *ModelConstraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.size – Get the total number of elements in the constraint.

ModelConstraint.slice – Create a slice constraint.

ModelConstraint.toString – Create a human readable string representation of the constraint.

RangedConstraint.lowerBoundCon – Get a constraint object representing the lower bound of the ranged constraint.

RangedConstraint.upperBoundCon – Get a constraint object representing the upper bound of the ranged constraint.

`RangedConstraint.lowerBoundCon`

<code>Constraint::t lowerBoundCon()</code>
--

Get a constraint object representing the lower bound of the ranged constraint.

Return (*Constraint*)

`RangedConstraint.upperBoundCon`

<code>Constraint::t upperBoundCon()</code>
--

Get a constraint object representing the upper bound of the ranged constraint.

Return (*Constraint*)

14.2.32 Class RangedVariable

`mosek::fusion::RangedVariable`

Defines a ranged variable.

Since this actually defines one variable with two inequalities, there will be two dual variables (slx and sux) corresponding to the lower and upper bounds. When asked for the dual solution, this variable will return ($y = \text{slx} - \text{sux}$), but in some cases this is not enough (the individual dual variables may be required by e.g. a certificate). The methods *RangedVariable.lowerBoundVar* and *RangedVariable.upperBoundVar* returns Variable objects that interface to the lower and upper bounds respectively.

Implements *ModelVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

RangedVariable.lowerBoundVar – Get a variable object representing to the lower bound of the ranged variable.

RangedVariable.upperBoundVar – Get a variable object representing to the upper bound of the ranged variable.

`RangedVariable.lowerBoundVar`

```
Variable::t lowerBoundVar()
```

Get a variable object representing to the lower bound of the ranged variable.

Return (*Variable*)

`RangedVariable.upperBoundVar`

```
Variable::t upperBoundVar()
```

Get a variable object representing to the upper bound of the ranged variable.

Return (*Variable*)

14.2.33 Class RepeatVariable

`mosek::fusion::RepeatVariable`

This class represents a variable repeating another variable.

Implements *BaseVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

14.2.34 Class Set

`mosek::fusion::Set`

This class is the abstract base class for shape specification objects.

Members *Set.compare* – Compare two sets.

Set.dim – Return the size of the requested dimension.

Set.getSize – Total number of elements in the set.

Set.getname – Return a string representing the item identified by the key.

Set.idxtokey – Convert a linear index to a N-dimensional key.

Set.realnd – Number of dimensions of more than 1 element, or 1 if the number of significant dimensions is 0.

Set.slice – Create a set object representing a slice of this set.

Set.stride – Return the stride size in the given dimension.

Set.toString – Return a string representation of the set.

Static members *Set.make* – Creates a set object.

Set.scalar – Create a set of size 1.

Implemented by *BaseSet*

`Set.compare`

```
bool compare(Set::t other)
```

Compare two sets and return true if they have the same shape and size. Note that the definition of **shape** only counts dimensions of size greater than 1. That is, compare will return true if a $N \times 1$ shape is compared with a $1 \times N$ shape.

Parameters *other* (*Set*) – The set to compare against.

Return (bool)

`Set.dim`

```
int dim(int i)
```

Return the size of the requested dimension.

Parameters *i* (int) – Dimension index.

Return (int)

`Set.getSize`

```
long long getSize()
```

Total number of elements in the set.

Return (long long)

Set.getname

```
string getname(long long key)
string getname(shared_ptr<ndarray<int,1>> keya)
```

Return a string representing the item identified by the key.

Parameters

- **key** (`long long`) – A linear index.
- **keya** (`int[]`) – A multi-dimensional index.

Return (`string`)**Set.idxtokey**

```
shared_ptr<ndarray<int,1>> idxtokey(long long idx)
```

Convert a linear index to a N-dimensional key.

Parameters **idx** (`long long`) – A linear index.

Return (`int[]`)

Set.make

```
Set::t Set::make(shared_ptr<ndarray<string,1>> names)
Set::t Set::make(int sz)
Set::t Set::make(int s1, int s2)
Set::t Set::make(int s1, int s2, int s3)
Set::t Set::make(shared_ptr<ndarray<int,1>> sizes)
Set::t Set::make(Set::t set1, Set::t set2)
Set::t Set::make(shared_ptr<ndarray<Set::t,1>> ss)
```

This static method is a factory for different kind of set objects:

- A (multi-dimensional) set of integers (shape).
- A set whose elements are strings.
- A set obtained as Cartesian product of sets given in a list.

Parameters

- **names** (`string[]`) – A list of strings for a set of strings.
- **sz** (`int`) – The size of a one-dimensional set of integers.
- **s1** (`int`) – Size of the first dimension.
- **s2** (`int`) – Size of the second dimension.
- **s3** (`int`) – Size of the third dimension.
- **sizes** (`int[]`) – The sizes of dimensions for a multi-dimensional integer set.
- **set1** ([*Set*](#)) – First factor in a Cartesian product.
- **set2** ([*Set*](#)) – Second factor in a Cartesian product.
- **ss** ([*Set*](#)[]) – Factors of the Cartesian product.

Return ([*Set*](#))

Set.realnd

```
int realnd()
```

Number of dimensions of more than 1 element, or 1 if the number of significant dimensions is 0.

Return (int)

Set.scalar

```
Set::t Set::scalar()
```

Create a set of size 1.

Return (*Set*)

Set.slice

```
Set::t slice(int first, int last)
Set::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Create a set object representing a slice of this set.

Parameters

- **first** (int) – First index in the range.
- **last** (int) – Last index in the range plus one.
- **firsta** (int[]) – First index in each dimension in the range.
- **lasta** (int[]) – Last index in each dimension in the range plus one.

Return (*Set*)

Set.stride

```
long long stride(int i)
```

Return the stride size in the given dimension.

Parameters **i** (int) – Dimension index.

Return (long long)

Set.toString

```
string toString()
```

Return a string representation of the set.

Return (string)

14.2.35 Class SliceConstraint

mosek::fusion::SliceConstraint

An alias for a subset of constraints from a single ModelConstraint.

This class acts as a proxy for accessing a portion of a ModelConstraint. It is possible to access and modify the properties of the original variable using this alias. It does not access the Model directly, only through the original variable.

Implements *Constraint*

Members *Constraint.add* – Add an expression to the constraint expression.

Constraint.dual – Get the dual solution values of the constraint.

Constraint.get_model – Get the model to which the constraint belongs.

Constraint.get_nd – Get the number of dimensions of the constraint.

Constraint.index – Get a single element from a constraint.

Constraint.level – Get the primal solution values of the constraint.

Constraint.shape – Return the constraint's shape.

Constraint.toString – Create a human readable string representation of the constraint.

SliceConstraint.size – Get the total number of elements in the constraint.

SliceConstraint.slice – Create a slice constraint.

Implemented by *BoundInterfaceConstraint*

`SliceConstraint.size`

```
long long size()
```

Get the total number of elements in the constraint.

Return (long long)

`SliceConstraint.slice`

```
Constraint::t slice(int first, int last)
Constraint::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Create a slice constraint.

Parameters

- **first** (int) – Index of the first element in the slice.
- **last** (int) – Index of the first element after the end of the slice.
- **firsta** (int[]) – The indexes of first elements in the slice along each dimension.
- **lasta** (int[]) – The indexes of first elements after the end of the slice along each dimension.

Return (*Constraint*)

14.2.36 Class SliceVariable

`mosek::fusion::SliceVariable`

An alias for a subset of variables from a single *ModelVariable*.

This class acts as a proxy for accessing a portion of a *ModelVariable*. It is possible to access and modify the properties of the original variable using this alias, and the object can be used in expressions as any other *Variable* object.

Implements *BaseVariable*

Members *BaseVariable.antidiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.toString – Create a string representation of the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

SliceVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

Implemented by *BoundInterfaceVariable*

`SliceVariable.slice`

```
Variable::t slice(int firstidx, int lastidx)
Variable::t slice(shared_ptr<ndarray<int,1>> firstidx, shared_ptr<ndarray<int,1>> lastidx)
```

Create a slice variable by picking a range of indexes for each variable dimension

Parameters

- `firstidx` (int)
- `firstidx` (int[])
- `lastidx` (int)
- `lastidx` (int[])

Return (*Variable*)

14.2.37 Class `SymLinearVariable`

`mosek::fusion::SymLinearVariable`

A linear variable defines a block of variables with the same linear domain. The domain is either a product of product of one-dimensional half-spaces (linear inequalities), a fixed value vector (equalities) or the whole space (free variables).

The *type* of a linear variable is immutable; it is either free, an inequality or an equality.

The class is not meant to be instantiated directly, but must be created by calling the *Model.variable* method.

Implements *ModelVariable*

Members *BaseVariable.antiDiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

SymLinearVariable.toString – Create a string representation of the variable.

SymLinearVariable.toString

```
string toString()
```

Create a string representation of the variable.

Return (string)

14.2.38 Class SymRangedVariable

`mosek::fusion::SymRangedVariable`

Defines a ranged variable.

Since this actually defines one variable with two inequalities, there will be two dual variables (slx and sux) corresponding to the lower and upper bounds. When asked for the dual solution, this variable will return (y=slx-sux), but in some cases this is not enough (the individual dual variables may be required by e.g. a certificate). The methods *RangedVariable.lowerBoundVar* and *RangedVariable.upperBoundVar* returns Variable objects that interface to the lower and upper bounds respectively.

Implements *ModelVariable*

Members *BaseVariable.antiDiag* – Return the antidiagonal of a square variable matrix.

BaseVariable.asExpr – Create an expression corresponding to the variable object.

BaseVariable.diag – Return the diagonal of a square variable matrix.

BaseVariable.dual – Get the dual solution value of the variable.

BaseVariable.getModel – Return the model to which the variable belongs.

BaseVariable.getShape – Return the shape of the variable.

BaseVariable.index – Return a variable slice of size 1 corresponding to a single element in the variable object..

BaseVariable.level – Get the primal solution value of the variable.

BaseVariable.makeContinuous – Drop integrality constraints on the variable, if any.

BaseVariable.makeInteger – Apply integrality constraints on the variable.

BaseVariable.pick – Create a slice variable by picking a list of indexes from this variable.

BaseVariable.setLevel – Input solution values for this variable

BaseVariable.shape – Return the shape of the variable.

BaseVariable.size – Get the number of elements in the variable.

BaseVariable.transpose – Transpose a vector or matrix variable

ModelVariable.slice – Create a slice variable by picking a range of indexes for each variable dimension

SymRangedVariable.toString – Create a string representation of the variable.

`SymRangedVariable.toString`

<code>string toString()</code>

Create a string representation of the variable.

Return (string)

14.2.39 Class SymmetricExpr

`mosek::fusion::SymmetricExpr`

A guaranteed symmetric square matrix expression.

It is defined as

$$\sum_i (M_i x_i) + b,$$

where : *math* : ‘ M_i ’ is a : *msk* : *func* : ‘SymmetricMatrix’ and : *math* : ‘ x_i ’ is a scalar variable.

Members *SymmetricExpr.toString* – Returns a human readable string representation of the expression.

`SymmetricExpr.toString`

<code>string toString()</code>

Returns a human readable string representation of the expression.

Return (string)

14.2.40 Class SymmetricLinearDomain

mosek::fusion::SymmetricLinearDomain

Represent a linear domain with symmetry.

Members *SymmetricLinearDomain.integral* – Creates a domain of integral variables.

SymmetricLinearDomain.sparse – Creates a domain exploiting sparsity.

SymmetricLinearDomain.integral

SymmetricLinearDomain::t integral()

Modify a given domain restricting its elements to be integral.

Return (*SymmetricLinearDomain*)

SymmetricLinearDomain.sparse

SymmetricLinearDomain::t sparse()

Modify a given domain exploiting sparsity, i.e only instantiating the variables that are actually used in the model.

Return (*SymmetricLinearDomain*)

14.2.41 Class SymmetricRangeDomain

mosek::fusion::SymmetricRangeDomain

Represent a ranged domain with symmetry.

Implements *RangeDomain*

Members *RangeDomain.integral* – Creates a domain of integral variables.

RangeDomain.sparse – Creates a domain exploiting sparsity.

RangeDomain.symmetric – Creates a symmetric domain.

14.2.42 Class SymmetricVariable

mosek::fusion::SymmetricVariable

In some cases using this variable instead of a standard *Variable* can reduce the number of instantiated variables by approximately 50%.

Implements *Variable*

Members *Variable.antidiag* – Return the anti-diagonal of a variable matrix.

Variable.asExpr – Create an expression corresponding to the variable object.

Variable.diag – Return the diagonal of a variable matrix.

Variable.dual – Get the dual solution value of the variable.

Variable.getModel – Return the model to which the variable belongs.

Variable.getShape – Return the shape of the variable.

Variable.index – Return a single entry in the variable.

Variable.level – Return the primal value of the variable as an array.

Variable.makeContinuous – Drop integrality constraints on the variable, if any.

Variable.makeInteger – Apply integrality constraints on the variable.

Variable.pick – Create a one-dimensional variable slice by picking a list of indexes from this variable.

Variable.setLevel – Input solution values for this variable

Variable.shape – Return the shape of the variable.

Variable.size – Get the number of elements in the variable.

Variable.slice – Create a slice variable by picking a range of indexes for each variable dimension.

Variable.toString – Create a string representation of the variable.

Variable.transpose – Transpose the variable.

Implemented by *SymRangedVariable*, *SymLinearVariable*, *PSDVariable*

14.2.43 Class Var

`mosek::fusion::Var`

Contains several static methods for manipulating variable objects and creating new variables from old ones.

Primal and dual solution values and additional operations on variables are available from the *Variable* class.

Static members *Var.compress* – Reshape a variable object by removing all dimensions of size 1.

Var.flatten – Create a one-dimensional logical view of a variable object.

Var.hrepeat – Repeat a variable a number of times in the second dimension.

Var.hstack – Stack a list of variables horizontally (i.e. along the second dimension).

Var.repeat – Repeat a variable a number of times in the given dimension.

Var.reshape – Create a reshaped version of the given variable.

Var.stack – Stack a list of variables in an arbitrary dimension.

Var.vrepeat – Repeat a variable a number of times in the first dimension.

Var.vstack – Stack a list of variables vertically (i.e. along the first dimension).

`Var.compress`

`Variable::t Var::compress(Variable::t v)`

Reshape a variable object by removing all dimensions of size 1. The result contains the same number of elements, but all dimensions are larger than 1 (except if the original variable contains exactly one element).

Parameters *v* (*Variable*) – The variable object to compress.

Return (*Variable*)

`Var.flatten`

`Variable::t Var::flatten(Variable::t v)`

Create a one-dimensional *Variable* object that represents a *logical* view of the k -dimensional variable V . The V matrix is traversed starting from the innermost dimension. For a two-dimensional matrix this means it is traversed row after row.

The returned view is a one-dimensional array of size equal to the product of dimensions of V .

Parameters v (*Variable*) – The variable to be flattened.

Return (*Variable*)

`Var.hrepeat`

```
Variable::t Var::hrepeat(Variable::t v, int n)
```

Repeat a variable a number of times in the second dimension. This is equivalent to horizontal stacking of n copies of the variable; see *Var.hstack*.

Parameters

- v (*Variable*) – A variable object.
- n (int) – Number of times to repeat v .

Return (*Variable*)

`Var.hstack`

```
Variable::t Var::hstack(shared_ptr<ndarray<Variable::t,1>> v)
Variable::t Var::hstack(Variable::t v1, Variable::t v2)
Variable::t Var::hstack(Variable::t v1, Variable::t v2, Variable::t v3)
```

Stack a list of variables horizontally (i.e. along the second dimension). The variables must have the same shape, except for the second dimension.

For example, if x^1, x^2, x^3 are three one-dimensional variables of length n then their horizontal stack is the matrix variable

$$\begin{bmatrix} | & | & | \\ x^1 & x^2 & x^3 \\ | & | & | \end{bmatrix}$$

of shape $(n,3)$.

Parameters

- v (*Variable*[]) – List of variables to stack.
- $v1$ (*Variable*) – First variable in the stack.
- $v2$ (*Variable*) – Second variable in the stack.
- $v3$ (*Variable*) – Third variable in the stack.

Return (*Variable*)

`Var.repeat`

```
Variable::t Var::repeat(Variable::t v, int dim, int n)
Variable::t Var::repeat(Variable::t v, int n)
```

Repeat a variable a number of times in the given dimension. If dim is non-negative this is equivalent to stacking n copies of the variable in dimension dim ; see *Var.stack*.

If dim is negative then a new dimension is added in front, so the new variable has shape $(n, v.\text{shape}())$.

The default is repeating in the first dimension as in *Var.vrepeat*.

Parameters

- v (*Variable*) – A variable object.
- dim (int) – Dimension to repeat in.
- n (int) – Number of times to repeat v .

Return (*Variable*)`Var.reshape`

```
Variable::t Var::reshape(Variable::t v, Set::t s)
Variable::t Var::reshape(Variable::t v, shared_ptr<ndarray<int,1>> dims)
Variable::t Var::reshape(Variable::t v, int d1, int d2)
Variable::t Var::reshape(Variable::t v, int d1)
```

Create a reshaped version of the given variable.

Parameters

- v (*Variable*) – A variable object.
- s (*Set*) – A set representing the new shape.
- dims ($\text{int}[]$) – An array containing the shape of the new variable.
- $d1$ (int) – Size of first dimension in the result.
- $d2$ (int) – Size of second dimension in the result.

Return (*Variable*)`Var.stack`

```
Variable::t Var::stack(shared_ptr<ndarray<Variable::t,1>> v, int dim)
Variable::t Var::stack(Variable::t v1, Variable::t v2, int dim)
Variable::t Var::stack(Variable::t v1, Variable::t v2, Variable::t v3, int dim)
Variable::t Var::stack(shared_ptr<ndarray<Variable::t,2>> vlist)
```

Stack a list of variables along an arbitrary dimension. All variables must have the same shape, except for dimension dim .

For example, suppose x, y are two matrix variables of shape $n \times m$. Then stacking them in the first dimension produces a matrix variable of shape $(2n, m)$:

$$\begin{bmatrix} x \\ y \end{bmatrix},$$

stacking them in the second dimension produces a matrix variable of shape $(n, 2m)$:

$$\begin{bmatrix} x & y \end{bmatrix},$$

and stacking them in the third dimension produces a three-dimensional variable of shape $(n, m, 2)$.

The version which takes a two-dimensional array of variables constructs a block matrix variable with the given variables as blocks. The dimensions of the blocks must be suitably compatible. The variables may be more than two-dimensional, if they have the same size in the remaining dimensions; the block stacking still takes place in the first and second dimension.

Parameters

- v (*Variable*[]) – List of variables to stack.
- dim (int) – Dimension in which to stack.
- $v1$ (*Variable*) – First variable in the stack.

- `v2` (*Variable*) – Second variable in the stack.
- `v3` (*Variable*) – Third variable in the stack.
- `vlist` (*Variable*[]) – List of variables to stack.

Return (*Variable*)

`Var.vrepeat`

```
Variable::t Var::vrepeat(Variable::t v, int n)
```

Repeat a variable a number of times in the first dimension. This is equivalent to vertically stacking of n copies of the variable; see *Var.vstack*.

Parameters

- `v` (*Variable*) – A variable object.
- `n` (int) – Number of times to repeat `v`.

Return (*Variable*)

`Var.vstack`

```
Variable::t Var::vstack(shared_ptr<ndarray<Variable::t,1>> v)
Variable::t Var::vstack(Variable::t v1, Variable::t v2)
Variable::t Var::vstack(Variable::t v1, Variable::t v2, Variable::t v3)
```

Stack a list of variables vertically (i.e. along the first dimension). The variables must have the same shape, except for the first dimension.

For example, if y^1, y^2, y^3 are three horizontal vector variables of length n (and shape $(1, n)$) then their vertical stack is the matrix variable

$$\begin{bmatrix} -y^1 - \\ -y^2 - \\ -y^3 - \end{bmatrix}$$

of shape $(3, n)$.

Parameters

- `v` (*Variable*[]) – List of variables to stack.
- `v1` (*Variable*) – First variable in the stack.
- `v2` (*Variable*) – Second variable in the stack.
- `v3` (*Variable*) – Third variable in the stack.

Return (*Variable*)

14.2.44 Class Variable

`mosek::fusion::Variable`

An abstract variable object. This is the base class for all variable types in *Fusion*, and it contains several static methods for manipulating variable objects.

The *Variable* object can be an interface to the normal model variables, e.g. *LinearVariable* and *ConicVariable*, to slices of other variables or to concatenations of other variables.

Primal and dual solution values can be accessed through the *Variable* object.

More static methods to manipulate variables are available in the *Var* class.

Members *Variable.antidiag* – Return the anti-diagonal of a variable matrix.

Variable.asExpr – Create an expression corresponding to the variable object.

Variable.diag – Return the diagonal of a variable matrix.

Variable.dual – Get the dual solution value of the variable.

Variable.getModel – Return the model to which the variable belongs.

Variable.getShape – Return the shape of the variable.

Variable.index – Return a single entry in the variable.

Variable.level – Return the primal value of the variable as an array.

Variable.makeContinuous – Drop integrality constraints on the variable, if any.

Variable.makeInteger – Apply integrality constraints on the variable.

Variable.pick – Create a one-dimensional variable slice by picking a list of indexes from this variable.

Variable.setLevel – Input solution values for this variable

Variable.shape – Return the shape of the variable.

Variable.size – Get the number of elements in the variable.

Variable.slice – Create a slice variable by picking a range of indexes for each variable dimension.

Variable.toString – Create a string representation of the variable.

Variable.transpose – Transpose the variable.

Implemented by *SymmetricVariable*, *BaseVariable*

Variable.antidiag

```
Variable::t antidiag(int index)
Variable::t antidiag()
```

Return the anti-diagonal of a variable matrix in a one-dimensional variable object. The main anti-diagonal is defined as starting with the element in the first row and last column.

Parameters *index* (int) – Index of the anti-diagonal. Index 0 means the main anti-diagonal, negative indices are below it and positive indices are above it.

Return (*Variable*)

Variable.asExpr

```
Expression::t asExpr()
```

Create an *Expression* object corresponding to $I \cdot V$, where I is the identity matrix and V is this variable.

Return (*Expression*)

Variable.diag

```
Variable::t diag(int index)
Variable::t diag()
```

Return the diagonal of a square variable matrix in a one-dimensional variable object. The main diagonal is defined as starting with the element in the first row and first column.

Parameters `index` (`int`) – Index of the diagonal. Index 0 means the main diagonal, negative indices are below it and positive indices are above it.

Return (*Variable*)

`Variable.dual`

```
shared_ptr<ndarray<double,1>> dual()
```

Get the dual solution value of the variable as an array. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

Return (`double[]`)

`Variable.getModel`

```
Model::t getModel()
```

Return the model to which the variable belongs.

Return (*Model*)

`Variable.getShape`

```
Set::t getShape()
```

Return the shape of the variable.

Return (*Set*)

`Variable.index`

```
Variable::t index(int i1)
Variable::t index(int i1, int i2)
Variable::t index(int i1, int i2, int i3)
Variable::t index(shared_ptr<ndarray<int,1>> idx)
```

Return a variable slice of size one corresponding to a single element in the variable object.

Parameters

- `i1` (`int`) – Index in the first dimension of the element requested.
- `i2` (`int`) – Index in the second dimension of the element requested.
- `i3` (`int`) – Index in the third dimension of the element requested.
- `idx` (`int[]`) – List of indexes of the elements requested.

Return (*Variable*)

`Variable.level`

```
shared_ptr<ndarray<double,1>> level()
```

Get the primal solution value of the variable as an array. When the selected slice is multi-dimensional, this corresponds to the flattened slice of solution values.

Return (`double[]`)

`Variable.makeContinuous`

```
void makeContinuous()
```

Drop integrality constraints on the variable, if any.

`Variable.makeInteger`

```
void makeInteger()
```

Apply integrality constraints on the variable.

`Variable.pick`

```
Variable::t pick(shared_ptr<ndarray<int,1>> idxs)
Variable::t pick(shared_ptr<ndarray<int,2>> midxs)
Variable::t pick(shared_ptr<ndarray<int,1>> i1, shared_ptr<ndarray<int,1>> i2)
Variable::t pick(shared_ptr<ndarray<int,1>> i1, shared_ptr<ndarray<int,1>> i2, shared_ptr
↪ <ndarray<int,1>> i3)
```

Create a one-dimensional variable slice by picking a list of indexes from this variable.

Parameters

- `idxs (int[])` – Indexes of the elements requested.
- `midxs (int[][])` – A sequence of multi-dimensional indexes of the elements requested.
- `i1 (int[])` – Index along the first dimension.
- `i2 (int[])` – Index along the second dimension.
- `i3 (int[])` – Index along the third dimension.

Return (*Variable*)

`Variable.setLevel`

```
void setLevel(shared_ptr<ndarray<double,1>> v)
```

Set values for an initial solution for this variable. Note that these values are buffered until the solver is called; they are not available through the `level()` methods.

Parameters `v (double[])` – An array of values to be assigned to the variable.

`Variable.shape`

```
Set::t shape()
```

Return the shape of the variable.

Return (*Set*)

`Variable.size`

```
long long size()
```

Get the number of elements in the variable.

Return (`long long`)

`Variable.slice`

```
Variable::t slice(int first, int last)
Variable::t slice(shared_ptr<ndarray<int,1>> firsta, shared_ptr<ndarray<int,1>> lasta)
```

Create a slice variable by picking a range of indexes for each variable dimension.

Parameters

- **first** (`int`) – The index from which the slice begins.
- **last** (`int`) – The index after the last element of the slice.
- **firsta** (`int[]`) – The indices from which the slice of a multidimensional variable begins.
- **lasta** (`int[]`) – The indices after the last element of slice of a multidimensional variable.

Return (*Variable*)

`Variable.toString`

```
string toString()
```

Create a string representation of the variable.

Return (`string`)

`Variable.transpose`

```
Variable::t transpose()
```

Return the transpose of the current variable. The variable must have at most two dimensions.

Return (*Variable*)

14.4 Parameters (alphabetical list sorted by type)

- *Double parameters*
- *Integer parameters*
- *String parameters*

14.4.1 Double parameters

"anaSolInfeasTol"

If a constraint violates its bound with an amount larger than this value, the constraint name, index and violation will be printed by the solution analyzer.

Default 1e-6

Accepted [0.0; +inf]

Groups *Analysis*

"basisRelTolS"

Maximum relative dual bound violation allowed in an optimal basic solution.

Default 1.0e-12

Accepted [0.0; +inf]

Groups *Simplex optimizer, Termination criteria*

"basisTolS"

Maximum absolute dual bound violation in an optimal basic solution.

Default 1.0e-6

Accepted [1.0e-9; +inf]

Groups *Simplex optimizer, Termination criteria*

"basisTolX"

Maximum absolute primal bound violation allowed in an optimal basic solution.

Default 1.0e-6

Accepted [1.0e-9; +inf]

Groups *Simplex optimizer, Termination criteria*

"intpntCoTolDfeas"

Dual feasibility tolerance used by the conic interior-point optimizer.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria, Conic interior-point method*

See also *intpntCoTolNearRel*

"intpntCoTolInfeas"

Controls when the conic interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Default 1.0e-10

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria, Conic interior-point method*

"intpntCoTolMuRed"

Relative complementarity gap feasibility tolerance used by the conic interior-point optimizer.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria, Conic interior-point method*

"intpntCoTolNearRel"

If **MOSEK** cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Default 1000

Accepted [1.0; +inf]

Groups *Interior-point method, Termination criteria, Conic interior-point method*

"intpntCoTolPfeas"

Primal feasibility tolerance used by the conic interior-point optimizer.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria, Conic interior-point method*

See also *intpntCoTolNearRel*

"intpntCoTolRelGap"

Relative gap termination tolerance used by the conic interior-point optimizer.

Default 1.0e-7

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria, Conic interior-point method*

See also *intpntCoTolNearRel*

"intpntQoTolDfeas"

Dual feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem..

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

See also *intpntQoTolNearRel*

"intpntQoTolInfeas"

Controls when the conic interior-point optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Default 1.0e-10

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

"intpntQoTolMuRed"

Relative complementarity gap feasibility tolerance used when interior-point optimizer is applied to a quadratic optimization problem.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

"intpntQoTolNearRel"

If MOSEK cannot compute a solution that has the prescribed accuracy, then it will multiply the termination tolerances with value of this parameter. If the solution then satisfies the termination criteria, then the solution is denoted near optimal, near feasible and so forth.

Default 1000

Accepted [1.0; +inf]

Groups *Interior-point method, Termination criteria*

"intpntQoTolPfeas"

Primal feasibility tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

See also *intpntQoTolNearRel*

"intpntQoTolRelGap"

Relative gap termination tolerance used when the interior-point optimizer is applied to a quadratic optimization problem.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

See also *intpntQoTolNearRel*

"intpntTolDfeas"

Dual feasibility tolerance used for linear optimization problems.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

"intpntTolDsafe"

Controls the initial dual starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it might be worthwhile to increase this value.

Default 1.0

Accepted [1.0e-4; +inf]

Groups *Interior-point method*

"intpntTolInfeas"

Controls when the optimizer declares the model primal or dual infeasible. A small number means the optimizer gets more conservative about declaring the model infeasible.

Default 1.0e-10

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria, Nonlinear convex method*

"intpntTolMuRed"

Relative complementarity gap tolerance for linear problems.

Default 1.0e-16

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

"intpntTolPath"

Controls how close the interior-point optimizer follows the central path. A large value of this parameter means the central is followed very closely. On numerical unstable problems it may be worthwhile to increase this parameter.

Default 1.0e-8

Accepted [0.0; 0.9999]

Groups *Interior-point method*

"intpntTolPfeas"

Primal feasibility tolerance used for linear optimization problems.

Default 1.0e-8

Accepted [0.0; 1.0]

Groups *Interior-point method, Termination criteria*

"intpntTolPsafe"

Controls the initial primal starting point used by the interior-point optimizer. If the interior-point optimizer converges slowly and/or the constraint or variable bounds are very large, then it may be worthwhile to increase this value.

Default 1.0

Accepted [1.0e-4; +inf]

Groups *Interior-point method*

"intpntTolRelGap"

Relative gap termination tolerance for linear problems.

Default 1.0e-8

Accepted [1.0e-14; +inf]

Groups *Termination criteria, Interior-point method*

"intpntTolRelStep"

Relative step size to the boundary for linear and quadratic optimization problems.

Default 0.9999

Accepted [1.0e-4; 0.999999]

Groups *Interior-point method*

"intpntTolStepSize"

Minimal step size tolerance. If the step size falls below the value of this parameter, then the interior-point optimizer assumes that it is stalled. In other words the interior-point optimizer does not make any progress and therefore it is better stop.

Default 1.0e-6

Accepted [0.0; 1.0]

Groups *Interior-point method*

"lowerObjCut"

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval [*lowerObjCut*, *upperObjCut*], then MOSEK is terminated.

Default -1.0e30

Accepted [-inf; +inf]

Groups *Termination criteria*

See also *lowerObjCutFiniteTrh*

"lowerObjCutFiniteTrh"

If the lower objective cut is less than the value of this parameter value, then the lower objective cut i.e. *lowerObjCut* is treated as $-\infty$.

Default -0.5e30

Accepted [-inf; +inf]

Groups *Termination criteria*

"mioDisableTermTime"

This parameter specifies the number of seconds n during which the termination criteria governed by

- *mioMaxNumRelaxs*
- *mioMaxNumBranches*
- *mioNearTolAbsGap*
- *mioNearTolRelGap*

is disabled since the beginning of the optimization.

A negative value is identical to infinity i.e. the termination criteria are never checked.

Default -1.0

Accepted [-inf; +inf]

Groups *Mixed-integer optimization, Termination criteria*

See also *mioMaxNumRelaxs*, *mioMaxNumBranches*, *mioNearTolAbsGap*, *mioNearTolRelGap*

"mioMaxTime"

This parameter limits the maximum time spent by the mixed-integer optimizer. A negative number means infinity.

Default -1.0

Accepted [-inf; +inf]

Groups *Mixed-integer optimization, Termination criteria*

"mioNearTolAbsGap"

Relaxed absolute optimality tolerance employed by the mixed-integer optimizer. This termination criteria is delayed. See *mioDisableTermTime* for details.

Default 0.0

Accepted [0.0; +inf]

Groups *Mixed-integer optimization*

See also *mioDisableTermTime*

"mioNearTolRelGap"

The mixed-integer optimizer is terminated when this tolerance is satisfied. This termination criteria is delayed. See *mioDisableTermTime* for details.

Default 1.0e-3

Accepted [0.0; +inf]

Groups *Mixed-integer optimization, Termination criteria*

See also *mioDisableTermTime*

"mioRelGapConst"

This value is used to compute the relative gap for the solution to an integer optimization problem.

Default 1.0e-10

Accepted [1.0e-15; +inf]

Groups *Mixed-integer optimization, Termination criteria*

"mioTolAbsGap"

Absolute optimality tolerance employed by the mixed-integer optimizer.

Default 0.0

Accepted [0.0; +inf]

Groups *Mixed-integer optimization*

"mioTolAbsRelaxInt"

Absolute integer feasibility tolerance. If the distance to the nearest integer is less than this tolerance then an integer constraint is assumed to be satisfied.

Default 1.0e-5

Accepted [1e-9; +inf]

Groups *Mixed-integer optimization*

"mioTolFeas"

Feasibility tolerance for mixed integer solver.

Default 1.0e-6

Accepted [1e-9; 1e-3]

Groups *Mixed-integer optimization*

"mioTolRelDualBoundImprovement"

If the relative improvement of the dual bound is smaller than this value, the solver will terminate the root cut generation. A value of 0.0 means that the value is selected automatically.

Default 0.0

Accepted [0.0; 1.0]

Groups *Mixed-integer optimization*

"mioTolRelGap"

Relative optimality tolerance employed by the mixed-integer optimizer.

Default 1.0e-4

Accepted [0.0; +inf]

Groups *Mixed-integer optimization, Termination criteria*

"optimizerMaxTime"

Maximum amount of time the optimizer is allowed to spent on the optimization. A negative number means infinity.

Default -1.0

Accepted [-inf; +inf]

Groups *Termination criteria*

"presolveTolAbsLindep"

Absolute tolerance employed by the linear dependency checker.

Default 1.0e-6

Accepted [0.0; +inf]

Groups *Presolve*

"presolveTolAij"

Absolute zero tolerance employed for a_{ij} in the presolve.

Default 1.0e-12

Accepted [1.0e-15; +inf]

Groups *Presolve*

"presolveTolRelLindep"

Relative tolerance employed by the linear dependency checker.

Default 1.0e-10

Accepted [0.0; +inf]

Groups *Presolve*

"presolveTolS"

Absolute zero tolerance employed for s_i in the presolve.

Default 1.0e-8

Accepted [0.0; +inf]

Groups *Presolve*

"presolveTolX"

Absolute zero tolerance employed for x_j in the presolve.

Default 1.0e-8

Accepted [0.0; +inf]

Groups *Presolve*

"simLuTolRelPiv"

Relative pivot tolerance employed when computing the LU factorization of the basis in the simplex optimizers and in the basis identification procedure.

A value closer to 1.0 generally improves numerical stability but typically also implies an increase in the computational work.

Default 0.01

Accepted [1.0e-6; 0.999999]

Groups *Basis identification, Simplex optimizer*

"simplexAbsTolPiv"

Absolute pivot tolerance employed by the simplex optimizers.

Default 1.0e-7

Accepted [1.0e-12; +inf]

Groups *Simplex optimizer*

"upperObjCut"

If either a primal or dual feasible solution is found proving that the optimal objective value is outside, the interval [*lowerObjCut*, *upperObjCut*], then **MOSEK** is terminated.

Default 1.0e30

Accepted [-inf; +inf]

Groups *Termination criteria*

See also *upperObjCutFiniteTrh*

"upperObjCutFiniteTrh"

If the upper objective cut is greater than the value of this parameter, then the upper objective cut *upperObjCut* is treated as ∞ .

Default 0.5e30

Accepted [-inf; +inf]

Groups *Termination criteria*

14.4.2 Integer parameters

"autoUpdateSolInfo"

Controls whether the solution information items are automatically updated after an optimization is performed.

Default *"off"*

Accepted *"on", "off"*

Groups *Overall system*

"biCleanOptimizer"

Controls which simplex optimizer is used in the clean-up phase.

Default *"free"*

Accepted *"free", "intpnt", "conic", "primalSimplex", "dualSimplex",
"freeSimplex", "mixedInt"*

Groups *Basis identification, Overall solver*

"biIgnoreMaxIter"

If the parameter *intpntBasis* has the value *"noError"* and the interior-point optimizer has terminated due to maximum number of iterations, then basis identification is performed if this parameter has the value *"on"*.

Default *"off"*

Accepted *"on", "off"*

Groups *Interior-point method, Basis identification*

"biIgnoreNumError"

If the parameter *intpntBasis* has the value *"noError"* and the interior-point optimizer has terminated due to a numerical problem, then basis identification is performed if this parameter has the value *"on"*.

Default *"off"*

Accepted *"on", "off"*

Groups *Interior-point method, Basis identification*

"biMaxIterations"

Controls the maximum number of simplex iterations allowed to optimize a basis after the basis identification.

Default *1000000*

Accepted *[0; +inf]*

Groups *Basis identification, Termination criteria*

"cacheLicense"

Specifies if the license is kept checked out for the lifetime of the mosek environment (*"on"*) or returned to the server immediately after the optimization (*"off"*).

By default the license is checked out for the lifetime of the **MOSEK** environment by the first call to the optimizer.

Check-in and check-out of licenses have an overhead. Frequent communication with the license server should be avoided.

Default *"on"*

Accepted *"on", "off"*

Groups *License manager*

"infeasPreferPrimal"

If both certificates of primal and dual infeasibility are supplied then only the primal is used when this option is turned on.

Default *"on"*

Accepted *"on", "off"*

Groups *Overall solver*

"intpntBasis"

Controls whether the interior-point optimizer also computes an optimal basis.

Default *"always"*

Accepted *"never", "always", "noError", "ifFeasible", "reserved"*

Groups *Interior-point method, Basis identification*

See also *biIgnoreMaxIter, biIgnoreNumError, biMaxIterations, biCleanOptimizer*

"intpntDiffStep"

Controls whether different step sizes are allowed in the primal and dual space.

Default *"on"*

Accepted

- *"on"*: Different step sizes are allowed.
- *"off"*: Different step sizes are not allowed.

Groups *Interior-point method*

"intpntMaxIterations"

Controls the maximum number of iterations allowed in the interior-point optimizer.

Default 400

Accepted [0; +inf]

Groups *Interior-point method, Termination criteria*

"intpntMaxNumCor"

Controls the maximum number of correctors allowed by the multiple corrector procedure. A negative value means that **MOSEK** is making the choice.

Default -1

Accepted [-1; +inf]

Groups *Interior-point method*

"intpntMultiThread"

Controls whether the interior-point optimizers are allowed to employ multiple threads if more threads is available.

Default *"on"*

Accepted *"on", "off"*

Groups *Overall system*

"intpntOffColTrh"

Controls how many offending columns are detected in the Jacobian of the constraint matrix.

0	no detection
1	aggressive detection
> 1	higher values mean less aggressive detection

Default 40

Accepted [0; +inf]

Groups *Interior-point method*

"intpntOrderMethod"

Controls the ordering strategy used by the interior-point optimizer when factorizing the Newton equation system.

Default *"free"*

Accepted *"free", "appminloc", "experimental", "tryGraphpar", "forceGraphpar", "none"*

Groups *Interior-point method*

"intpntRegularizationUse"

Controls whether regularization is allowed.

Default *"on"*

Accepted *"on", "off"*

Groups *Interior-point method*

"intpntScaling"

Controls how the problem is scaled before the interior-point optimizer is used.

Default *"free"*

Accepted *"free", "none", "moderate", "aggressive"*

Groups *Interior-point method*

"intpntSolveForm"

Controls whether the primal or the dual problem is solved.

Default *"free"*

Accepted *"free", "primal", "dual"*

Groups *Interior-point method*

"intpntStartingPoint"

Starting point used by the interior-point optimizer.

Default *"free"*

Accepted *"free", "guess", "constant", "satisfyBounds"*

Groups *Interior-point method*

"licenseDebug"

This option is used to turn on debugging of the license manager.

Default *"off"*

Accepted *"on", "off"*

Groups *License manager*

"licensePauseTime"

If *licenseWait* = *"on"* and no license is available, then **MOSEK** sleeps a number of milliseconds between each check of whether a license has become free.

Default 100

Accepted [0; 1000000]

Groups *License manager*

"licenseSuppressExpireWrns"

Controls whether license features expire warnings are suppressed.

Default *"off"*

Accepted *"on", "off"*

Groups *License manager, Output information*

"licenseTrhExpiryWrn"

If a license feature expires in a numbers days less than the value of this parameter then a warning will be issued.

Default 7

Accepted [0; +inf]

Groups *License manager, Output information*

"licenseWait"

If all licenses are in use **MOSEK** returns with an error code. However, by turning on this parameter **MOSEK** will wait for an available license.

Default "off"

Accepted "on", "off"

Groups *Overall solver, Overall system, License manager*

"log"

Controls the amount of log information. The value 0 implies that all log information is suppressed. A higher level implies that more information is logged.

Please note that if a task is employed to solve a sequence of optimization problems the value of this parameter is reduced by the value of *logCutSecondOpt* for the second and any subsequent optimizations.

Default 10

Accepted [0; +inf]

Groups *Output information, Logging*

See also *logCutSecondOpt*

"logAnaPro"

Controls amount of output from the problem analyzer.

Default 1

Accepted [0; +inf]

Groups *Analysis, Logging*

"logBi"

Controls the amount of output printed by the basis identification procedure. A higher level implies that more information is logged.

Default 1

Accepted [0; +inf]

Groups *Basis identification, Output information, Logging*

"logBiFreq"

Controls how frequent the optimizer outputs information about the basis identification and how frequent the user-defined callback function is called.

Default 2500

Accepted [0; +inf]

Groups *Basis identification, Output information, Logging*

"logCutSecondOpt"

If a task is employed to solve a sequence of optimization problems, then the value of the log levels is reduced by the value of this parameter. E.g *log* and *logSim* are reduced by the value of this parameter for the second and any subsequent optimizations.

Default 1

Accepted [0; +inf]

Groups *Output information, Logging*

See also *log, logIntpnt, logMio, logSim*

"logExpand"

Controls the amount of logging when a data item such as the maximum number constrains is expanded.

Default 0

Accepted [0; +inf]

Groups *Output information, Logging*

"logFile"

If turned on, then some log info is printed when a file is written or read.

Default 1

Accepted [0; +inf]

Groups *Data input/output, Output information, Logging*

"logInfeasAna"

Controls amount of output printed by the infeasibility analyzer procedures. A higher level implies that more information is logged.

Default 1

Accepted [0; +inf]

Groups *Infeasibility report, Output information, Logging*

"logIntpnt"

Controls amount of output printed by the interior-point optimizer. A higher level implies that more information is logged.

Default 1

Accepted [0; +inf]

Groups *Interior-point method, Output information, Logging*

"logMio"

Controls the log level for the mixed-integer optimizer. A higher level implies that more information is logged.

Default 4

Accepted [0; +inf]

Groups *Mixed-integer optimization, Output information, Logging*

"logMioFreq"

Controls how frequent the mixed-integer optimizer prints the log line. It will print line every time *logMioFreq* relaxations have been solved.

Default 10

Accepted [-inf; +inf]

Groups *Mixed-integer optimization, Output information, Logging*

"logOrder"

If turned on, then factor lines are added to the log.

Default 1

Accepted [0; +inf]

Groups *Output information, Logging*

"logPresolve"

Controls amount of output printed by the presolve procedure. A higher level implies that more information is logged.

Default 1

Accepted [0; +inf]

Groups *Logging*

"logResponse"

Controls amount of output printed when response codes are reported. A higher level implies that more information is logged.

Default 0

Accepted [0; +inf]

Groups *Output information, Logging*

"logSim"

Controls amount of output printed by the simplex optimizer. A higher level implies that more information is logged.

Default 4

Accepted [0; +inf]

Groups *Simplex optimizer, Output information, Logging*

"logSimFreq"

Controls how frequent the simplex optimizer outputs information about the optimization and how frequent the user-defined callback function is called.

Default 1000

Accepted [0; +inf]

Groups *Simplex optimizer, Output information, Logging*

"logSimMinor"

Currently not in use.

Default 1

Accepted [0; +inf]

Groups *Simplex optimizer, Output information*

"mioBranchDir"

Controls whether the mixed-integer optimizer is branching up or down by default.

Default *"free"*

Accepted *"free", "up", "down", "near", "far", "rootLp", "guided", "pseudocost"*

Groups *Mixed-integer optimization*

"mioConstructSol"

If set to *"on"* and all integer variables have been given a value for which a feasible mixed integer solution exists, then **MOSEK** generates an initial solution to the mixed integer problem by fixing all integer values and solving the remaining problem.

Default *"off"*

Accepted *"on", "off"*

Groups *Mixed-integer optimization*

"mioCutClique"

Controls whether clique cuts should be generated.

Default *"on"*

Accepted

- *"on"*: Turns generation of this cut class on.
- *"off"*: Turns generation of this cut class off.

Groups *Mixed-integer optimization*

"mioCutCmir"

Controls whether mixed integer rounding cuts should be generated.

Default *"on"*

Accepted

- *"on"*: Turns generation of this cut class on.
- *"off"*: Turns generation of this cut class off.

Groups *Mixed-integer optimization*

"mioCutGmi"

Controls whether GMI cuts should be generated.

Default *"on"*

Accepted

- *"on"*: Turns generation of this cut class on.
- *"off"*: Turns generation of this cut class off.

Groups *Mixed-integer optimization*

"mioCutImpliedBound"

Controls whether implied bound cuts should be generated.

Default *"off"*

Accepted

- *"on"*: Turns generation of this cut class on.
- *"off"*: Turns generation of this cut class off.

Groups *Mixed-integer optimization*

"mioCutKnapsackCover"

Controls whether knapsack cover cuts should be generated.

Default *"off"*

Accepted

- *"on"*: Turns generation of this cut class on.
- *"off"*: Turns generation of this cut class off.

Groups *Mixed-integer optimization*

"mioCutSelectionLevel"

Controls how aggressively generated cuts are selected to be included in the relaxation.

-1. The optimizer chooses the level of cut selection

0. Generated cuts less likely to be added to the relaxation

1. Cuts are more aggressively selected to be included in the relaxation

Default -1

Accepted [-1; +1]

Groups *Mixed-integer optimization***"mioHeuristicLevel"**

Controls the heuristic employed by the mixed-integer optimizer to locate an initial good integer feasible solution. A value of zero means the heuristic is not used at all. A larger value than 0 means that a gradually more sophisticated heuristic is used which is computationally more expensive. A negative value implies that the optimizer chooses the heuristic. Normally a value around 3 to 5 should be optimal.

Default -1

Accepted [-inf; +inf]

Groups *Mixed-integer optimization*

"mioMaxNumBranches"

Maximum number of branches allowed during the branch and bound search. A negative value means infinite.

Default -1

Accepted [-inf; +inf]

Groups *Mixed-integer optimization, Termination criteria*

See also *mioDisableTermTime*

"mioMaxNumRelaxs"

Maximum number of relaxations allowed during the branch and bound search. A negative value means infinite.

Default -1

Accepted [-inf; +inf]

Groups *Mixed-integer optimization*

See also *mioDisableTermTime*

"mioMaxNumSolutions"

The mixed-integer optimizer can be terminated after a certain number of different feasible solutions has been located. If this parameter has the value $n > 0$, then the mixed-integer optimizer will be terminated when n feasible solutions have been located.

Default -1

Accepted [-inf; +inf]

Groups *Mixed-integer optimization, Termination criteria*

See also *mioDisableTermTime*

"mioMode"

Controls whether the optimizer includes the integer restrictions when solving a (mixed) integer optimization problem.

Default *"satisfied"*

Accepted *"ignored", "satisfied"*

Groups *Overall solver*

"mioNodeOptimizer"

Controls which optimizer is employed at the non-root nodes in the mixed-integer optimizer.

Default *"free"*

Accepted *"free", "intpnt", "conic", "primalSimplex", "dualSimplex", "freeSimplex", "mixedInt"*

Groups *Mixed-integer optimization*

"mioNodeSelection"

Controls the node selection strategy employed by the mixed-integer optimizer.

Default *"free"*

Accepted *"free", "first", "best", "worst", "hybrid", "pseudo"*

Groups *Mixed-integer optimization*

"mioPerspectiveReformulate"

Enables or disables perspective reformulation in presolve.

Default *"on"*

Accepted *"on", "off"*

Groups *Mixed-integer optimization*

"mioProbingLevel"

Controls the amount of probing employed by the mixed-integer optimizer in presolve.

-1. The optimizer chooses the level of probing employed

0. Probing is disabled

1. A low amount of probing is employed

2. A medium amount of probing is employed

3. A high amount of probing is employed

Default *-1*

Accepted *[-1; 3]*

Groups *Mixed-integer optimization*

"mioRinsMaxNodes"

Controls the maximum number of nodes allowed in each call to the RINS heuristic. The default value of -1 means that the value is determined automatically. A value of zero turns off the heuristic.

Default *-1*

Accepted *[-1; +inf]*

Groups *Mixed-integer optimization*

"mioRootOptimizer"

Controls which optimizer is employed at the root node in the mixed-integer optimizer.

Default *"free"*

Accepted *"free", "intpnt", "conic", "primalSimplex", "dualSimplex", "freeSimplex", "mixedInt"*

Groups *Mixed-integer optimization*

"mioRootRepeatPresolveLevel"

Controls whether presolve can be repeated at root node.

- -1 The optimizer chooses whether presolve is repeated
- 0 Never repeat presolve
- 1 Always repeat presolve

Default *-1*

Accepted *[-1; 1]*

Groups *Mixed-integer optimization*

"mioVbDetectionLevel"

Controls how much effort is put into detecting variable bounds.

-1. The optimizer chooses

0. No variable bounds are detected

1. Only detect variable bounds that are directly represented in the problem

2. Detect variable bounds in probing

Default -1

Accepted [-1; +2]

Groups *Mixed-integer optimization*

"mtSpincount"

Set the number of iterations to spin before sleeping.

Default 0

Accepted [0; 1000000000]

Groups *Overall system*

"numThreads"

Controls the number of threads employed by the optimizer. If set to 0 the number of threads used will be equal to the number of cores detected on the machine.

Default 0

Accepted [0; +inf]

Groups *Overall system*

"optimizer"

The parameter controls which optimizer is used to optimize the task.

Default *"free"*

Accepted *"free", "intpnt", "conic", "primalSimplex", "dualSimplex", "freeSimplex", "mixedInt"*

Groups *Overall solver*

"presolveEliminatorMaxFill"

Controls the maximum amount of fill-in that can be created by one pivot in the elimination phase of the presolve. A negative value means the parameter value is selected automatically.

Default -1

Accepted [-inf; +inf]

Groups *Presolve*

"presolveEliminatorMaxNumTries"

Control the maximum number of times the eliminator is tried. A negative value implies MOSEK decides.

Default -1

Accepted [-inf; +inf]

Groups *Presolve*

"presolveLevel"

Currently not used.

Default -1

Accepted [-inf; +inf]

Groups *Overall solver, Presolve*

"presolveLindepAbsWorkTrh"

The linear dependency check is potentially computationally expensive.

Default 100

Accepted [-inf; +inf]

Groups *Presolve*

"presolveLindepRelWorkTrh"

The linear dependency check is potentially computationally expensive.

Default 100

Accepted [-inf; +inf]

Groups *Presolve*

"presolveLindepUse"

Controls whether the linear constraints are checked for linear dependencies.

Default *"on"*

Accepted

- *"on"*: Turns the linear dependency check on.
- *"off"*: Turns the linear dependency check off.

Groups *Presolve*

"presolveUse"

Controls whether the presolve is applied to a problem before it is optimized.

Default *"free"*

Accepted *"off", "on", "free"*

Groups *Overall solver, Presolve*

"removeUnusedSolutions"

Removes unused solutions before the optimization is performed.

Default *"off"*

Accepted *"on", "off"*

Groups *Overall system*

"simBasisFactorUse"

Controls whether an LU factorization of the basis is used in a hot-start. Forcing a refactorization sometimes improves the stability of the simplex optimizers, but in most cases there is a performance penalty.

Default *"on"*

Accepted *"on", "off"*

Groups *Simplex optimizer*

"simDegen"

Controls how aggressively degeneration is handled.

Default *"free"*

Accepted *"none", "free", "aggressive", "moderate", "minimum"*

Groups *Simplex optimizer*

"simDualCrash"

Controls whether crashing is performed in the dual simplex optimizer.

If this parameter is set to x , then a crash will be performed if a basis consists of more than $(100 - x)$ mod f_v entries, where f_v is the number of fixed variables.

Default 90

Accepted [0; +inf]

Groups *Dual simplex*

"simDualPhaseoneMethod"

An experimental feature.

Default 0

Accepted [0; 10]

Groups *Simplex optimizer*

"simDualRestrictSelection"

The dual simplex optimizer can use a so-called restricted selection/pricing strategy to choose the outgoing variable. Hence, if restricted selection is applied, then the dual simplex optimizer first choose a subset of all the potential outgoing variables. Next, for some time it will choose the outgoing variable only among the subset. From time to time the subset is redefined.

A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Default 50

Accepted [0; 100]

Groups *Dual simplex*

"simDualSelection"

Controls the choice of the incoming variable, known as the selection strategy, in the dual simplex optimizer.

Default *"free"*

Accepted *"free", "full", "ase", "devea", "se", "partial"*

Groups *Dual simplex*

"simExploitDupvec"

Controls if the simplex optimizers are allowed to exploit duplicated columns.

Default *"off"*

Accepted *"on", "off", "free"*

Groups *Simplex optimizer*

"simHotstart"

Controls the type of hot-start that the simplex optimizer perform.

Default *"free"*

Accepted *"none", "free", "statusKeys"*

Groups *Simplex optimizer*

"simHotstartLu"

Determines if the simplex optimizer should exploit the initial factorization.

Default *"on"*

Accepted

- *"on"*: Factorization is reused if possible.

- *"off"*: Factorization is recomputed.

Groups *Simplex optimizer*

"simMaxIterations"

Maximum number of iterations that can be used by a simplex optimizer.

Default 10000000

Accepted [0; +inf]

Groups *Simplex optimizer, Termination criteria*

"simMaxNumSetbacks"

Controls how many set-backs are allowed within a simplex optimizer. A set-back is an event where the optimizer moves in the wrong direction. This is impossible in theory but may happen due to numerical problems.

Default 250

Accepted [0; +inf]

Groups *Simplex optimizer*

"simNonSingular"

Controls if the simplex optimizer ensures a non-singular basis, if possible.

Default *"on"*

Accepted *"on"*, *"off"*

Groups *Simplex optimizer*

"simPrimalCrash"

Controls whether crashing is performed in the primal simplex optimizer.

In general, if a basis consists of more than (100-this parameter value)% fixed variables, then a crash will be performed.

Default 90

Accepted [0; +inf]

Groups *Primal simplex*

"simPrimalPhaseoneMethod"

An experimental feature.

Default 0

Accepted [0; 10]

Groups *Simplex optimizer*

"simPrimalRestrictSelection"

The primal simplex optimizer can use a so-called restricted selection/pricing strategy to choose the outgoing variable. Hence, if restricted selection is applied, then the primal simplex optimizer first choose a subset of all the potential incoming variables. Next, for some time it will choose the incoming variable only among the subset. From time to time the subset is redefined.

A larger value of this parameter implies that the optimizer will be more aggressive in its restriction strategy, i.e. a value of 0 implies that the restriction strategy is not applied at all.

Default 50

Accepted [0; 100]

Groups *Primal simplex*

"simPrimalSelection"

Controls the choice of the incoming variable, known as the selection strategy, in the primal simplex optimizer.

Default *"free"*

Accepted *"free", "full", "ase", "deveæ", "se", "partial"*

Groups *Primal simplex*

"simRefactorFreq"

Controls how frequent the basis is refactorized. The value 0 means that the optimizer determines the best point of refactorization.

It is strongly recommended NOT to change this parameter.

Default 0

Accepted [0; +inf]

Groups *Simplex optimizer*

"simReformulation"

Controls if the simplex optimizers are allowed to reformulate the problem.

Default *"off"*

Accepted *"on", "off", "free", "aggressive"*

Groups *Simplex optimizer*

"simSaveLu"

Controls if the LU factorization stored should be replaced with the LU factorization corresponding to the initial basis.

Default *"off"*

Accepted *"on", "off"*

Groups *Simplex optimizer*

"simScaling"

Controls how much effort is used in scaling the problem before a simplex optimizer is used.

Default *"free"*

Accepted *"free", "none", "moderate", "aggressive"*

Groups *Simplex optimizer*

"simScalingMethod"

Controls how the problem is scaled before a simplex optimizer is used.

Default *"pow2"*

Accepted *"pow2", "free"*

Groups *Simplex optimizer*

"simSolveForm"

Controls whether the primal or the dual problem is solved by the primal-/dual-simplex optimizer.

Default *"free"*

Accepted *"free", "primal", "dual"*

Groups *Simplex optimizer*

"simSwitchOptimizer"

The simplex optimizer sometimes chooses to solve the dual problem instead of the primal problem. This implies that if you have chosen to use the dual simplex optimizer and the problem is dualized, then it actually makes sense to use the primal simplex optimizer instead. If this parameter is on and the problem is dualized and furthermore the simplex optimizer is chosen to be the primal (dual) one, then it is switched to the dual (primal).

Default *"off"*

Accepted *"on", "off"*

Groups *Simplex optimizer*

"writeLpFullObj"

Write all variables, including the ones with 0-coefficients, in the objective.

Default *"on"*

Accepted *"on", "off"*

Groups *Data input/output*

"writeLpLineWidth"

Maximum width of line in an LP file written by **MOSEK**.

Default 80

Accepted [40; +inf]

Groups *Data input/output*

"writeLpQuotedNames"

If this option is turned on, then **MOSEK** will quote invalid LP names when writing an LP file.

Default *"on"*

Accepted *"on", "off"*

Groups *Data input/output*

"writeLpTermsPerLine"

Maximum number of terms on a single line in an LP file written by **MOSEK**. 0 means unlimited.

Default 10

Accepted [0; +inf]

Groups *Data input/output*

14.4.3 String parameters

"basSolFileName"

Name of the bas solution file.

Accepted Any valid file name.

Groups *Data input/output, Solution input/output*

"dataFileName"

Data are read and written to this file.

Accepted Any valid file name.

Groups *Data input/output*

"intSolFileName"

Name of the int solution file.

Accepted Any valid file name.

Groups *Data input/output, Solution input/output*

"itrSolFileName"

Name of the itr solution file.

Accepted Any valid file name.

Groups *Data input/output, Solution input/output*

"remoteAccessToken"

An access token used to submit tasks to a remote **MOSEK** server. An access token is a random 32-byte string encoded in base64, i.e. it is a 44 character ASCII string.

Accepted Any valid string.

Groups *Overall system*

"writeLpGenVarName"

Sometimes when an LP file is written additional variables must be inserted. They will have the prefix denoted by this parameter.

Default xmskgen

Accepted Any valid string.

Groups *Data input/output*

14.5 Enumerations

AccSolutionStatus

Constants used for defining which solutions statuses are acceptable.

Anything

Accept all solution status except *SolutionStatus.Undefined*.

Optimal

Accept only optimal solution status.

NearOptimal

Accept only at least near optimal solution status.

Feasible

Accept any feasible solution, even if not optimal.

Certificate

Accept only a certificate.

ObjectiveSense

Used in *Model.objective* to define the objective sense of the *Model*.

Undefined

The sense is not defined; trying to optimize a *Model* whose objective sense is undefined is an error.

Minimize

Minimize the objective.

Maximize

Maximize the objective.

ProblemStatus

Constants defining the problem status.

Unknown

Unknown problem status.

PrimalAndDualFeasible

The problem is feasible.

PrimalFeasible

The problem is at least primal feasible.

DualFeasible

The problem is at least least dual feasible.

PrimalInfeasible

The problem is primal infeasible.

DualInfeasible

The problem is dual infeasible.

PrimalAndDualInfeasible

The problem is primal and dual infeasible.

IllPosed

The problem is illposed.

PrimalInfeasibleOrUnbounded

The problem is primal infeasible or unbounded.

SolutionStatus

Defines properties of either a primal or a dual solution. A model may contain multiple solutions which may have different status. Specifically, there will be individual solutions, and thus solution statuses, for the interior-point, simplex and integer solvers.

Undefined

Undefined solution. This means that no values exist for the relevant solution.

Unknown

The solution status is unknown; this will happen if the user inputs values or a solution is read from a file or the solver stalled.

Optimal

The solution values are feasible and optimal.

NearOptimal

The solution values are feasible and nearly optimal.

Feasible

The solution is feasible.

NearFeasible

The solution is nearly feasible.

Certificate

The solution is a certificate of infeasibility (primal or dual, depending on which solution it belongs to).

NearCertificate

The solution is nearly a certificate of infeasibility (primal or dual, depending on which solution it belongs to).

IllposedCert

The solution is a certificate of illposedness.

SolutionType

Used when requesting a specific solution from a *Model*.

Default

Auto-select the default solution; usually this will be the integer solution, if available, otherwise the basic solution, if available, otherwise the interior-point solution.

Basic

Select the basic solution.

Interior

Select the interior-point solution.

Integer

Select the integer solution.

14.6 Constants

14.6.1 Language selection constants

"eng"
English language selection

"dan"
Danish language selection

14.6.2 Constraint or variable access modes. All functions using this enum are deprecated. Use separate functions for rows/columns instead.

"var"
Access data by columns (variable oriented)

"con"
Access data by rows (constraint oriented)

14.6.3 Basis identification

"never"
Never do basis identification.

"always"
Basis identification is always performed even if the interior-point optimizer terminates abnormally.

"noError"
Basis identification is performed if the interior-point optimizer terminates without an error.

"ifFeasible"
Basis identification is not performed if the interior-point optimizer terminates with a problem status saying that the problem is primal or dual infeasible.

"reserved"
Not currently in use.

14.6.4 Bound keys

"lo"
The constraint or variable has a finite lower bound and an infinite upper bound.

"up"
The constraint or variable has an infinite lower bound and an finite upper bound.

"fx"
The constraint or variable is fixed.

"fr"
The constraint or variable is free.

"ra"
The constraint or variable is ranged.

14.6.5 Mark

"lo"
The lower bound is selected for sensitivity analysis.

"up"

The upper bound is selected for sensitivity analysis.

14.6.6 Degeneracy strategies

"none"

The simplex optimizer should use no degeneration strategy.

"free"

The simplex optimizer chooses the degeneration strategy.

"aggressive"

The simplex optimizer should use an aggressive degeneration strategy.

"moderate"

The simplex optimizer should use a moderate degeneration strategy.

"minimum"

The simplex optimizer should use a minimum degeneration strategy.

14.6.7 Transposed matrix.

"no"

No transpose is applied.

"yes"

A transpose is applied.

14.6.8 Triangular part of a symmetric matrix.

"lo"

Lower part.

"up"

Upper part

14.6.9 Problem reformulation.

"on"

Allow the simplex optimizer to reformulate the problem.

"off"

Disallow the simplex optimizer to reformulate the problem.

"free"

The simplex optimizer can choose freely.

"aggressive"

The simplex optimizer should use an aggressive reformulation strategy.

14.6.10 Exploit duplicate columns.

"on"

Allow the simplex optimizer to exploit duplicated columns.

"off"

Disallow the simplex optimizer to exploit duplicated columns.

"free"

The simplex optimizer can choose freely.

14.6.11 Hot-start type employed by the simplex optimizer

"none"

The simplex optimizer performs a coldstart.

"free"

The simplex optimizer chooses the hot-start type.

"statusKeys"

Only the status keys of the constraints and variables are used to choose the type of hot-start.

14.6.12 Hot-start type employed by the interior-point optimizers.

"none"

The interior-point optimizer performs a coldstart.

"primal"

The interior-point optimizer exploits the primal solution only.

"dual"

The interior-point optimizer exploits the dual solution only.

"primalDual"

The interior-point optimizer exploits both the primal and dual solution.

14.6.13 Progress callback codes

"beginBi"

The basis identification procedure has been started.

"beginConic"

The callback function is called when the conic optimizer is started.

"beginDualBi"

The callback function is called from within the basis identification procedure when the dual phase is started.

"beginDualSensitivity"

Dual sensitivity analysis is started.

"beginDualSetupBi"

The callback function is called when the dual BI phase is started.

"beginDualSimplex"

The callback function is called when the dual simplex optimizer started.

"beginDualSimplexBi"

The callback function is called from within the basis identification procedure when the dual simplex clean-up phase is started.

"beginFullConvexityCheck"

Begin full convexity check.

"beginInfeasAna"

The callback function is called when the infeasibility analyzer is started.

"beginIntpnt"

The callback function is called when the interior-point optimizer is started.

"beginLicenseWait"
Begin waiting for license.

"beginMio"
The callback function is called when the mixed-integer optimizer is started.

"beginOptimizer"
The callback function is called when the optimizer is started.

"beginPresolve"
The callback function is called when the presolve is started.

"beginPrimalBi"
The callback function is called from within the basis identification procedure when the primal phase is started.

"beginPrimalRepair"
Begin primal feasibility repair.

"beginPrimalSensitivity"
Primal sensitivity analysis is started.

"beginPrimalSetupBi"
The callback function is called when the primal BI setup is started.

"beginPrimalSimplex"
The callback function is called when the primal simplex optimizer is started.

"beginPrimalSimplexBi"
The callback function is called from within the basis identification procedure when the primal simplex clean-up phase is started.

"beginQcqpReformulate"
Begin QCQP reformulation.

"beginRead"
MOSEK has started reading a problem file.

"beginRootCutgen"
The callback function is called when root cut generation is started.

"beginSimplex"
The callback function is called when the simplex optimizer is started.

"beginSimplexBi"
The callback function is called from within the basis identification procedure when the simplex clean-up phase is started.

"beginToConic"
Begin conic reformulation.

"beginWrite"
MOSEK has started writing a problem file.

"conic"
The callback function is called from within the conic optimizer after the information database has been updated.

"dualSimplex"
The callback function is called from within the dual simplex optimizer.

"endBi"
The callback function is called when the basis identification procedure is terminated.

"endConic"
The callback function is called when the conic optimizer is terminated.

"endDualBi"
The callback function is called from within the basis identification procedure when the dual phase is terminated.

"endDualSensitivity"
Dual sensitivity analysis is terminated.

"endDualSetupBi"
The callback function is called when the dual BI phase is terminated.

"endDualSimplex"
The callback function is called when the dual simplex optimizer is terminated.

"endDualSimplexBi"
The callback function is called from within the basis identification procedure when the dual clean-up phase is terminated.

"endFullConvexityCheck"
End full convexity check.

"endInfeasAna"
The callback function is called when the infeasibility analyzer is terminated.

"endIntpnt"
The callback function is called when the interior-point optimizer is terminated.

"endLicenseWait"
End waiting for license.

"endMio"
The callback function is called when the mixed-integer optimizer is terminated.

"endOptimizer"
The callback function is called when the optimizer is terminated.

"endPresolve"
The callback function is called when the presolve is completed.

"endPrimalBi"
The callback function is called from within the basis identification procedure when the primal phase is terminated.

"endPrimalRepair"
End primal feasibility repair.

"endPrimalSensitivity"
Primal sensitivity analysis is terminated.

"endPrimalSetupBi"
The callback function is called when the primal BI setup is terminated.

"endPrimalSimplex"
The callback function is called when the primal simplex optimizer is terminated.

"endPrimalSimplexBi"
The callback function is called from within the basis identification procedure when the primal clean-up phase is terminated.

"endQcqpReformulate"
End QCQP reformulation.

"endRead"
MOSEK has finished reading a problem file.

"endRootCutgen"
The callback function is called when root cut generation is terminated.

"endSimplex"
The callback function is called when the simplex optimizer is terminated.

"endSimplexBi"

The callback function is called from within the basis identification procedure when the simplex clean-up phase is terminated.

"endToConic"

End conic reformulation.

"endWrite"

MOSEK has finished writing a problem file.

"imBi"

The callback function is called from within the basis identification procedure at an intermediate point.

"imConic"

The callback function is called at an intermediate stage within the conic optimizer where the information database has not been updated.

"imDualBi"

The callback function is called from within the basis identification procedure at an intermediate point in the dual phase.

"imDualSensitivity"

The callback function is called at an intermediate stage of the dual sensitivity analysis.

"imDualSimplex"

The callback function is called at an intermediate point in the dual simplex optimizer.

"imFullConvexityCheck"

The callback function is called at an intermediate stage of the full convexity check.

"imIntpnt"

The callback function is called at an intermediate stage within the interior-point optimizer where the information database has not been updated.

"imLicenseWait"

MOSEK is waiting for a license.

"imLu"

The callback function is called from within the LU factorization procedure at an intermediate point.

"imMio"

The callback function is called at an intermediate point in the mixed-integer optimizer.

"imMioDualSimplex"

The callback function is called at an intermediate point in the mixed-integer optimizer while running the dual simplex optimizer.

"imMioIntpnt"

The callback function is called at an intermediate point in the mixed-integer optimizer while running the interior-point optimizer.

"imMioPrimalSimplex"

The callback function is called at an intermediate point in the mixed-integer optimizer while running the primal simplex optimizer.

"imOrder"

The callback function is called from within the matrix ordering procedure at an intermediate point.

"imPresolve"

The callback function is called from within the presolve procedure at an intermediate stage.

"imPrimalBi"

The callback function is called from within the basis identification procedure at an intermediate point in the primal phase.

"imPrimalSensitivity"

The callback function is called at an intermediate stage of the primal sensitivity analysis.

"imPrimalSimplex"

The callback function is called at an intermediate point in the primal simplex optimizer.

"imQoReformulate"

The callback function is called at an intermediate stage of the conic quadratic reformulation.

"imRead"

Intermediate stage in reading.

"imRootCutgen"

The callback is called from within root cut generation at an intermediate stage.

"imSimplex"

The callback function is called from within the simplex optimizer at an intermediate point.

"imSimplexBi"

The callback function is called from within the basis identification procedure at an intermediate point in the simplex clean-up phase. The frequency of the callbacks is controlled by the *logSimFreq* parameter.

"intpnt"

The callback function is called from within the interior-point optimizer after the information database has been updated.

"newIntMio"

The callback function is called after a new integer solution has been located by the mixed-integer optimizer.

"primalSimplex"

The callback function is called from within the primal simplex optimizer.

"readOpf"

The callback function is called from the OPF reader.

"readOpfSection"

A chunk of Q non-zeros has been read from a problem file.

"solvingRemote"

The callback function is called while the task is being solved on a remote server.

"updateDualBi"

The callback function is called from within the basis identification procedure at an intermediate point in the dual phase.

"updateDualSimplex"

The callback function is called in the dual simplex optimizer.

"updateDualSimplexBi"

The callback function is called from within the basis identification procedure at an intermediate point in the dual simplex clean-up phase. The frequency of the callbacks is controlled by the *logSimFreq* parameter.

"updatePresolve"

The callback function is called from within the presolve procedure.

"updatePrimalBi"

The callback function is called from within the basis identification procedure at an intermediate point in the primal phase.

"updatePrimalSimplex"

The callback function is called in the primal simplex optimizer.

"updatePrimalSimplexBi"

The callback function is called from within the basis identification procedure at an intermediate point in the primal simplex clean-up phase. The frequency of the callbacks is controlled by the *logSimFreq* parameter.

"writeOpf"

The callback function is called from the OPF writer.

14.6.14 Types of convexity checks.

"none"

No convexity check.

"simple"

Perform simple and fast convexity check.

"full"

Perform a full convexity check.

14.6.15 Compression types

"none"

No compression is used.

"free"

The type of compression used is chosen automatically.

"gzip"

The type of compression used is gzip compatible.

14.6.16 Cone types

"quad"

The cone is a quadratic cone.

"rquad"

The cone is a rotated quadratic cone.

14.6.17 Name types

"gen"

General names. However, no duplicate and blank names are allowed.

"mps"

MPS type names.

"lp"

LP type names.

14.6.18 Cone types

"sparse"

Sparse symmetric matrix.

14.6.19 Data format types

"extension"

The file extension is used to determine the data file format.

"mps"

The data file is MPS formatted.

"lp"
The data file is LP formatted.

"op"
The data file is an optimization problem formatted file.

"xml"
The data file is an XML formatted file.

"freeMps"
The data a free MPS formatted file.

"task"
Generic task dump file.

"cb"
Conic benchmark format,

"jsonTask"
JSON based task format.

14.6.20 Double information items

"biCleanDualTime"
Time spent within the dual clean-up optimizer of the basis identification procedure since its invocation.

"biCleanPrimalTime"
Time spent within the primal clean-up optimizer of the basis identification procedure since its invocation.

"biCleanTime"
Time spent within the clean-up phase of the basis identification procedure since its invocation.

"biDualTime"
Time spent within the dual phase basis identification procedure since its invocation.

"biPrimalTime"
Time spent within the primal phase of the basis identification procedure since its invocation.

"biTime"
Time spent within the basis identification procedure since its invocation.

"intpntDualFeas"
Dual feasibility measure reported by the interior-point optimizer. (For the interior-point optimizer this measure is not directly related to the original problem because a homogeneous model is employed.)

"intpntDualObj"
Dual objective value reported by the interior-point optimizer.

"intpntFactorNumFlops"
An estimate of the number of flops used in the factorization.

"intpntOptStatus"
A measure of optimality of the solution. It should converge to +1 if the problem has a primal-dual optimal solution, and converge to -1 if the problem is (strictly) primal or dual infeasible. If the measure converges to another constant, or fails to settle, the problem is usually ill-posed.

"intpntOrderTime"
Order time (in seconds).

"intpntPrimalFeas"
Primal feasibility measure reported by the interior-point optimizer. (For the interior-point optimizer this measure is not directly related to the original problem because a homogeneous model is employed).

"intpntPrimalObj"

Primal objective value reported by the interior-point optimizer.

"intpntTime"

Time spent within the interior-point optimizer since its invocation.

"mioCliqueSeparationTime"

Seperation time for clique cuts.

"mioCmirSeparationTime"

Seperation time for CMIR cuts.

"mioConstructSolutionObj"

If **MOSEK** has successfully constructed an integer feasible solution, then this item contains the optimal objective value corresponding to the feasible solution.

"mioDualBoundAfterPresolve"

Value of the dual bound after presolve but before cut generation.

"mioGmiSeparationTime"

Seperation time for GMI cuts.

"mioHeuristicTime"

Total time spent in the optimizer.

"mioImpliedBoundTime"

Seperation time for implied bound cuts.

"mioKnapsackCoverSeparationTime"

Seperation time for knapsack cover.

"mioObjAbsGap"

Given the mixed-integer optimizer has computed a feasible solution and a bound on the optimal objective value, then this item contains the absolute gap defined by

$$|(\text{objective value of feasible solution}) - (\text{objective bound})|.$$

Otherwise it has the value -1.0.

"mioObjBound"

The best known bound on the objective function. This value is undefined until at least one relaxation has been solved: To see if this is the case check that *"mioNumRelax"* is strictly positive.

"mioObjInt"

The primal objective value corresponding to the best integer feasible solution. Please note that at least one integer feasible solution must have been located i.e. check *"mioNumIntSolutions"*.

"mioObjRelGap"

Given that the mixed-integer optimizer has computed a feasible solution and a bound on the optimal objective value, then this item contains the relative gap defined by

$$\frac{|(\text{objective value of feasible solution}) - (\text{objective bound})|}{\max(\delta, |(\text{objective value of feasible solution})|)}.$$

where δ is given by the parameter *mioRelGapConst*. Otherwise it has the value -1.0 .

"mioOptimizerTime"

Total time spent in the optimizer.

"mioProbingTime"

Total time for probing.

"mioRootCutgenTime"

Total time for cut generation.

"mioRootOptimizerTime"

Time spent in the optimizer while solving the root relaxation.

"mioRootPresolveTime"
Time spent in while presolving the root relaxation.

"mioTime"
Time spent in the mixed-integer optimizer.

"mioUserObjCut"
If the objective cut is used, then this information item has the value of the cut.

"optimizerTime"
Total time spent in the optimizer since it was invoked.

"presolveEliTime"
Total time spent in the eliminator since the presolve was invoked.

"presolveLindepTime"
Total time spent in the linear dependency checker since the presolve was invoked.

"presolveTime"
Total time (in seconds) spent in the presolve since it was invoked.

"primalRepairPenaltyObj"
The optimal objective value of the penalty function.

"qcqoReformulateMaxPerturbation"
Maximum absolute diagonal perturbation occurring during the QCQO reformulation.

"qcqoReformulateTime"
Time spent with conic quadratic reformulation.

"qcqoReformulateWorstCholeskyColumnScaling"
Worst Cholesky column scaling.

"qcqoReformulateWorstCholeskyDiagScaling"
Worst Cholesky diagonal scaling.

"rdTime"
Time spent reading the data file.

"simDualTime"
Time spent in the dual simplex optimizer since invoking it.

"simFeas"
Feasibility measure reported by the simplex optimizer.

"simObj"
Objective value reported by the simplex optimizer.

"simPrimalTime"
Time spent in the primal simplex optimizer since invoking it.

"simTime"
Time spent in the simplex optimizer since invoking it.

"solBasDualObj"
Dual objective value of the basic solution.

"solBasDviolcon"
Maximal dual bound violation for x^c in the basic solution.

"solBasDviolvar"
Maximal dual bound violation for x^x in the basic solution.

"solBasNrmBarx"
Infinity norm of \overline{X} in the basic solution.

"solBasNrmSlc"
Infinity norm of s_l^c in the basic solution.

"solBasNrmSlx"
Infinity norm of s_l^x in the basic solution.

"solBasNrmSuc"
Infinity norm of s_u^c in the basic solution.

"solBasNrmSux"
Infinity norm of s_u^X in the basic solution.

"solBasNrmXc"
Infinity norm of x^c in the basic solution.

"solBasNrmXx"
Infinity norm of x^x in the basic solution.

"solBasNrmY"
Infinity norm of y in the basic solution.

"solBasPrimalObj"
Primal objective value of the basic solution.

"solBasPviolcon"
Maximal primal bound violation for x^c in the basic solution.

"solBasPviolvar"
Maximal primal bound violation for x^x in the basic solution.

"solItgNrmBarx"
Infinity norm of \bar{X} in the integer solution.

"solItgNrmXc"
Infinity norm of x^c in the integer solution.

"solItgNrmXx"
Infinity norm of x^x in the integer solution.

"solItgPrimalObj"
Primal objective value of the integer solution.

"solItgPviolbarvar"
Maximal primal bound violation for \bar{X} in the integer solution.

"solItgPviolcon"
Maximal primal bound violation for x^c in the integer solution.

"solItgPviolcones"
Maximal primal violation for primal conic constraints in the integer solution.

"solItgPviolitg"
Maximal violation for the integer constraints in the integer solution.

"solItgPviolvar"
Maximal primal bound violation for x^x in the integer solution.

"solItrDualObj"
Dual objective value of the interior-point solution.

"solItrDviolbarvar"
Maximal dual bound violation for \bar{X} in the interior-point solution.

"solItrDviolcon"
Maximal dual bound violation for x^c in the interior-point solution.

"solItrDviolcones"
Maximal dual violation for dual conic constraints in the interior-point solution.

"solItrDviolvar"
Maximal dual bound violation for x^x in the interior-point solution.

"solItrNrmBars"
Infinity norm of \bar{S} in the interior-point solution.

"solItrNrmBarx"
Infinity norm of \bar{X} in the interior-point solution.

"solItrNrmSlc"
Infinity norm of s_l^c in the interior-point solution.

"solItrNrmSlx"
Infinity norm of s_l^x in the interior-point solution.

"solItrNrmSnx"
Infinity norm of s_n^x in the interior-point solution.

"solItrNrmSuc"
Infinity norm of s_u^c in the interior-point solution.

"solItrNrmSux"
Infinity norm of s_u^X in the interior-point solution.

"solItrNrmXc"
Infinity norm of x^c in the interior-point solution.

"solItrNrmXx"
Infinity norm of x^x in the interior-point solution.

"solItrNrmY"
Infinity norm of y in the interior-point solution.

"solItrPrimalObj"
Primal objective value of the interior-point solution.

"solItrPviolbarvar"
Maximal primal bound violation for \bar{X} in the interior-point solution.

"solItrPviolcon"
Maximal primal bound violation for x^c in the interior-point solution.

"solItrPviolcones"
Maximal primal violation for primal conic constraints in the interior-point solution.

"solItrPviolvar"
Maximal primal bound violation for x^x in the interior-point solution.

"toConicTime"
Time spent in the last to conic reformulation.

14.6.21 License feature

"pts"
Base system.

"pton"
Nonlinear extension.

14.6.22 Long integer information items.

"biCleanDualDegIter"
Number of dual degenerate clean iterations performed in the basis identification.

"biCleanDualIter"
Number of dual clean iterations performed in the basis identification.

"biCleanPrimalDegIter"

Number of primal degenerate clean iterations performed in the basis identification.

"biCleanPrimalIter"

Number of primal clean iterations performed in the basis identification.

"biDualIter"

Number of dual pivots performed in the basis identification.

"biPrimalIter"

Number of primal pivots performed in the basis identification.

"intpntFactorNumNz"

Number of non-zeros in factorization.

"mioIntpntIter"

Number of interior-point iterations performed by the mixed-integer optimizer.

"mioPresolvedAnz"

Number of non-zero entries in the constraint matrix of presolved problem.

"mioSimMaxiterSetbacks"

Number of times the the simplex optimizer has hit the maximum iteration limit when re-optimizing.

"mioSimplexIter"

Number of simplex iterations performed by the mixed-integer optimizer.

"rdNumanz"

Number of non-zeros in A that is read.

"rdNumqnz"

Number of Q non-zeros.

14.6.23 Integer information items.

"anaProNumCon"

Number of constraints in the problem.

"anaProNumConEq"

Number of equality constraints.

"anaProNumConFr"

Number of unbounded constraints.

"anaProNumConLo"

Number of constraints with a lower bound and an infinite upper bound.

"anaProNumConRa"

Number of constraints with finite lower and upper bounds.

"anaProNumConUp"

Number of constraints with an upper bound and an infinite lower bound.

"anaProNumVar"

Number of variables in the problem.

"anaProNumVarBin"

Number of binary (0-1) variables.

"anaProNumVarCont"

Number of continuous variables.

"anaProNumVarEq"

Number of fixed variables.

"anaProNumVarFr"

Number of free variables.

"anaProNumVarInt"	Number of general integer variables.
"anaProNumVarLo"	Number of variables with a lower bound and an infinite upper bound.
"anaProNumVarRa"	Number of variables with finite lower and upper bounds.
"anaProNumVarUp"	Number of variables with an upper bound and an infinite lower bound. This value is set by
"intpntFactorDimDense"	Dimension of the dense sub system in factorization.
"intpntIter"	Number of interior-point iterations since invoking the interior-point optimizer.
"intpntNumThreads"	Number of threads that the interior-point optimizer is using.
"intpntSolveDual"	Non-zero if the interior-point optimizer is solving the dual problem.
"mioAbsgapSatisfied"	Non-zero if absolute gap is within tolerances.
"mioCliqueTableSize"	Size of the clique table.
"mioConstructNumRoundings"	Number of values in the integer solution that is rounded to an integer value.
"mioConstructSolution"	If this item has the value 0, then MOSEK did not try to construct an initial integer feasible solution. If the item has a positive value, then MOSEK successfully constructed an initial integer feasible solution.
"mioInitialSolution"	Is non-zero if an initial integer solution is specified.
"mioNearAbsgapSatisfied"	Non-zero if absolute gap is within relaxed tolerances.
"mioNearRelgapSatisfied"	Non-zero if relative gap is within relaxed tolerances.
"mioNodeDepth"	Depth of the last node solved.
"mioNumActiveNodes"	Number of active branch bound nodes.
"mioNumBranch"	Number of branches performed during the optimization.
"mioNumCliqueCuts"	Number of clique cuts.
"mioNumCmirCuts"	Number of Complemented Mixed Integer Rounding (CMIR) cuts.
"mioNumGomoryCuts"	Number of Gomory cuts.
"mioNumImpliedBoundCuts"	Number of implied bound cuts.

"mioNumIntSolutions"
Number of integer feasible solutions that has been found.

"mioNumKnapsackCoverCuts"
Number of clique cuts.

"mioNumRelax"
Number of relaxations solved during the optimization.

"mioNumRepeatedPresolve"
Number of times presolve was repeated at root.

"mioNumcon"
Number of constraints in the problem solved by the mixed-integer optimizer.

"mioNumint"
Number of integer variables in the problem solved by the mixed-integer optimizer.

"mioNumvar"
Number of variables in the problem solved by the mixed-integer optimizer.

"mioObjBoundDefined"
Non-zero if a valid objective bound has been found, otherwise zero.

"mioPresolvedNumbin"
Number of binary variables in the problem solved by the mixed-integer optimizer.

"mioPresolvedNumcon"
Number of constraints in the presolved problem.

"mioPresolvedNumcont"
Number of continuous variables in the problem solved by the mixed-integer optimizer.

"mioPresolvedNumint"
Number of integer variables in the presolved problem.

"mioPresolvedNumvar"
Number of variables in the presolved problem.

"mioRelgapSatisfied"
Non-zero if relative gap is within tolerances.

"mioTotalNumCuts"
Total number of cuts generated by the mixed-integer optimizer.

"mioUserObjCut"
If it is non-zero, then the objective cut is used.

"optNumcon"
Number of constraints in the problem solved when the optimizer is called.

"optNumvar"
Number of variables in the problem solved when the optimizer is called

"optimizeResponse"
The response code returned by optimize.

"rdNumbarvar"
Number of variables read.

"rdNumcon"
Number of constraints read.

"rdNumcone"
Number of conic constraints read.

"rdNumintvar"
Number of integer-constrained variables read.

"rdNumq"
Number of nonempty Q matrices read.

"rdNumvar"
Number of variables read.

"rdPrototype"
Problem type.

"simDualDegIter"
The number of dual degenerate iterations.

"simDualHotstart"
If 1 then the dual simplex algorithm is solving from an advanced basis.

"simDualHotstartLu"
If 1 then a valid basis factorization of full rank was located and used by the dual simplex algorithm.

"simDualInfIter"
The number of iterations taken with dual infeasibility.

"simDualIter"
Number of dual simplex iterations during the last optimization.

"simNumcon"
Number of constraints in the problem solved by the simplex optimizer.

"simNumvar"
Number of variables in the problem solved by the simplex optimizer.

"simPrimalDegIter"
The number of primal degenerate iterations.

"simPrimalHotstart"
If 1 then the primal simplex algorithm is solving from an advanced basis.

"simPrimalHotstartLu"
If 1 then a valid basis factorization of full rank was located and used by the primal simplex algorithm.

"simPrimalInfIter"
The number of iterations taken with primal infeasibility.

"simPrimalIter"
Number of primal simplex iterations during the last optimization.

"simSolveDual"
Is non-zero if dual problem is solved.

"solBasProsta"
Problem status of the basic solution. Updated after each optimization.

"solBasSolsta"
Solution status of the basic solution. Updated after each optimization.

"solItgProsta"
Problem status of the integer solution. Updated after each optimization.

"solItgSolsta"
Solution status of the integer solution. Updated after each optimization.

"solItrProsta"
Problem status of the interior-point solution. Updated after each optimization.

"solItrSolsta"
Solution status of the interior-point solution. Updated after each optimization.

"stoNumARealloc"

Number of times the storage for storing A has been changed. A large value may indicate that memory fragmentation may occur.

14.6.24 Information item types

"douType"

Is a double information type.

"intType"

Is an integer.

"lintType"

Is a long integer.

14.6.25 Input/output modes

"read"

The file is read-only.

"write"

The file is write-only. If the file exists then it is truncated when it is opened. Otherwise it is created when it is opened.

"readwrite"

The file is to read and written.

14.6.26 Specifies the branching direction.

"free"

The mixed-integer optimizer decides which branch to choose.

"up"

The mixed-integer optimizer always chooses the up branch first.

"down"

The mixed-integer optimizer always chooses the down branch first.

"near"

Branch in direction nearest to selected fractional variable.

"far"

Branch in direction farthest from selected fractional variable.

"rootLp"

Chose direction based on root lp value of selected variable.

"guided"

Branch in direction of current incumbent.

"pseudocost"

Branch based on the pseudocost of the variable.

14.6.27 Continuous mixed-integer solution type

"none"

No interior-point or basic solution are reported when the mixed-integer optimizer is used.

"root"

The reported interior-point and basic solutions are a solution to the root node problem when mixed-integer optimizer is used.

"itg"

The reported interior-point and basic solutions are a solution to the problem with all integer variables fixed at the value they have in the integer solution. A solution is only reported in case the problem has a primal feasible solution.

"itgRel"

In case the problem is primal feasible then the reported interior-point and basic solutions are a solution to the problem with all integer variables fixed at the value they have in the integer solution. If the problem is primal infeasible, then the solution to the root node problem is reported.

14.6.28 Integer restrictions

"ignored"

The integer constraints are ignored and the problem is solved as a continuous problem.

"satisfied"

Integer restrictions should be satisfied.

14.6.29 Mixed-integer node selection types

"free"

The optimizer decides the node selection strategy.

"first"

The optimizer employs a depth first node selection strategy.

"best"

The optimizer employs a best bound node selection strategy.

"worst"

The optimizer employs a worst bound node selection strategy.

"hybrid"

The optimizer employs a hybrid strategy.

"pseudo"

The optimizer employs selects the node based on a pseudo cost estimate.

14.6.30 MPS file format type

"strict"

It is assumed that the input file satisfies the MPS format strictly.

"relaxed"

It is assumed that the input file satisfies a slightly relaxed version of the MPS format.

"free"

It is assumed that the input file satisfies the free MPS format. This implies that spaces are not allowed in names. Otherwise the format is free.

"cplex"

The CPLEX compatible version of the MPS format is employed.

14.6.31 Objective sense types

"minimize"

The problem should be minimized.

"maximize"

The problem should be maximized.

14.6.32 On/off

"on"

Switch the option on.

"off"

Switch the option off.

14.6.33 Optimizer types

"conic"

The optimizer for problems having conic constraints.

"dualSimplex"

The dual simplex optimizer is used.

"free"

The optimizer is chosen automatically.

"freeSimplex"

One of the simplex optimizers is used.

"intpnt"

The interior-point optimizer is used.

"mixedInt"

The mixed-integer optimizer.

"primalSimplex"

The primal simplex optimizer is used.

14.6.34 Ordering strategies

"free"

The ordering method is chosen automatically.

"appminloc"

Approximate minimum local fill-in ordering is employed.

"experimental"

This option should not be used.

"tryGraphpar"

Always try the graph partitioning based ordering.

"forceGraphpar"

Always use the graph partitioning based ordering even if it is worse than the approximate minimum local fill ordering.

"none"

No ordering is used.

14.6.35 Presolve method.

"off"

The problem is not presolved before it is optimized.

"on"

The problem is presolved before it is optimized.

"free"

It is decided automatically whether to presolve before the problem is optimized.

14.6.36 Parameter type

"invalidType"

Not a valid parameter.

"douType"

Is a double parameter.

"intType"

Is an integer parameter.

"strType"

Is a string parameter.

14.6.37 Problem data items

"var"

Item is a variable.

"con"

Item is a constraint.

"cone"

Item is a cone.

14.6.38 Problem types

"lo"

The problem is a linear optimization problem.

"qo"

The problem is a quadratic optimization problem.

"qcqo"

The problem is a quadratically constrained optimization problem.

"geco"

General convex optimization.

"conic"

A conic optimization.

"mixed"

General nonlinear constraints and conic constraints. This combination can not be solved by MOSEK.

14.6.39 Problem status keys

"unknown"

Unknown problem status.

"primAndDualFeas"

The problem is primal and dual feasible.

"primFeas"

The problem is primal feasible.

"dualFeas"

The problem is dual feasible.

"nearPrimAndDualFeas"

The problem is at least nearly primal and dual feasible.

"nearPrimFeas"

The problem is at least nearly primal feasible.

"nearDualFeas"

The problem is at least nearly dual feasible.

"primInfeas"

The problem is primal infeasible.

"dualInfeas"

The problem is dual infeasible.

"primAndDualInfeas"

The problem is primal and dual infeasible.

"illPosed"

The problem is ill-posed. For example, it may be primal and dual feasible but have a positive duality gap.

"primInfeasOrUnbounded"

The problem is either primal infeasible or unbounded. This may occur for mixed-integer problems.

14.6.40 XML writer output mode

"row"

Write in row order.

"col"

Write in column order.

14.6.41 Response code type

"ok"

The response code is OK.

"wrn"

The response code is a warning.

"trm"

The response code is an optimizer termination status.

"err"

The response code is an error.

"unk"

The response code does not belong to any class.

14.6.42 Scaling type

"free"

The optimizer chooses the scaling heuristic.

"none"

No scaling is performed.

"moderate"

A conservative scaling is performed.

"aggressive"

A very aggressive scaling is performed.

14.6.43 Scaling method

"pow2"

Scales only with power of 2 leaving the mantissa untouched.

"free"

The optimizer chooses the scaling heuristic.

14.6.44 Sensitivity types

"basis"

Basis sensitivity analysis is performed.

"optimalPartition"

Optimal partition sensitivity analysis is performed.

14.6.45 Simplex selection strategy

"free"

The optimizer chooses the pricing strategy.

"full"

The optimizer uses full pricing.

"ase"

The optimizer uses approximate steepest-edge pricing.

"devex"

The optimizer uses devex steepest-edge pricing (or if it is not available an approximate steep-edge selection).

"se"

The optimizer uses steepest-edge selection (or if it is not available an approximate steep-edge selection).

"partial"

The optimizer uses a partial selection approach. The approach is usually beneficial if the number of variables is much larger than the number of constraints.

14.6.46 Solution items

"xc"

Solution for the constraints.

"xx"

Variable solution.

"y"

Lagrange multipliers for equations.

"slc"

Lagrange multipliers for lower bounds on the constraints.

"suc"

Lagrange multipliers for upper bounds on the constraints.

"slx"

Lagrange multipliers for lower bounds on the variables.

"sux"

Lagrange multipliers for upper bounds on the variables.

"snx"

Lagrange multipliers corresponding to the conic constraints on the variables.

14.6.47 Solution status keys

"unknown"

Status of the solution is unknown.

"optimal"

The solution is optimal.

"primFeas"

The solution is primal feasible.

"dualFeas"

The solution is dual feasible.

"primAndDualFeas"

The solution is both primal and dual feasible.

"nearOptimal"

The solution is nearly optimal.

"nearPrimFeas"

The solution is nearly primal feasible.

"nearDualFeas"

The solution is nearly dual feasible.

"nearPrimAndDualFeas"

The solution is nearly both primal and dual feasible.

"primInfeasCer"

The solution is a certificate of primal infeasibility.

"dualInfeasCer"

The solution is a certificate of dual infeasibility.

"nearPrimInfeasCer"

The solution is almost a certificate of primal infeasibility.

"nearDualInfeasCer"

The solution is almost a certificate of dual infeasibility.

"primIllposedCer"

The solution is a certificate that the primal problem is illposed.

"dualIllposedCer"

The solution is a certificate that the dual problem is illposed.

"integerOptimal"

The primal solution is integer optimal.

"nearIntegerOptimal"

The primal solution is near integer optimal.

14.6.48 Solution types

"bas"

The basic solution.

"itr"

The interior solution.

"itg"

The integer solution.

14.6.49 Solve primal or dual form

"free"

The optimizer is free to solve either the primal or the dual problem.

"primal"

The optimizer should solve the primal problem.

"dual"

The optimizer should solve the dual problem.

14.6.50 Status keys

"unk"

The status for the constraint or variable is unknown.

"bas"

The constraint or variable is in the basis.

"supbas"

The constraint or variable is super basic.

"low"

The constraint or variable is at its lower bound.

"upr"

The constraint or variable is at its upper bound.

"fix"

The constraint or variable is fixed.

"inf"

The constraint or variable is infeasible in the bounds.

14.6.51 Starting point types

"free"

The starting point is chosen automatically.

"guess"

The optimizer guesses a starting point.

"constant"

The optimizer constructs a starting point by assigning a constant value to all primal and dual variables. This starting point is normally robust.

"satisfyBounds"

The starting point is chosen to satisfy all the simple bounds on nonlinear variables. If this starting point is employed, then more care than usual should be employed when choosing the bounds on the nonlinear variables. In particular very tight bounds should be avoided.

14.6.52 Stream types

"log"

Log stream. Contains the aggregated contents of all other streams. This means that a message written to any other stream will also be written to this stream.

"msg"

Message stream. Log information relating to performance and progress of the optimization is written to this stream.

"err"

Error stream. Error messages are written to this stream.

"wrn"

Warning stream. Warning messages are written to this stream.

14.6.53 Integer values

"maxStrLen"

Maximum string length allowed in MOSEK.

"licenseBufferLength"

The length of a license key buffer.

14.6.54 Variable types

"typeCont"

Is a continuous variable.

"typeInt"

Is an integer variable.

14.7 Exceptions

- *DimensionError*: Thrown when a given object has the wrong number of dimensions, or they have not the right size.
- *DomainError*: Invalid domain.
- *ExpressionError*: Tried to construct an expression from invalid.
- *FatalError*: A fatal error has happened.
- *FusionException*: Base class for all normal exceptions in fusion.
- *FusionRuntimeException*: Base class for all run-time exceptions in fusion.
- *IDError*: Error when reading or writing a stream, or opening a file.
- *IndexError*: Index out of bound, or a multi-dimensional index had wrong number of dimensions.
- *LengthError*: An array did not have the required length, or two arrays were expected to have same length.
- *MatrixError*: Thrown if data used in construction of a matrix contained inconsistencies or errors.
- *ModelError*: Thrown when objects from different models were mixed.
- *NameError*: Name clash; tries to add a variable or constraint with a name that already exists.
- *OptimizeError*: An error occurred during optimization.
- *ParameterError*: Tried to use an invalid parameter for a value that was invalid for a specific parameter.
- *RangeError*: Invalid range specified
- *SetDefinitionError*: Invalid data for constructing set.
- *SliceError*: Invalid slice definition, negative slice or slice index out of bounds.

- *SolutionError*: Requested a solution that was undefined or whose status was not acceptable.
- *SparseFormatError*: The given sparsity patterns was invalid or specified an index that was out of bounds.
- *UnexpectedError*: An unexpected error has happened. No specific exception could have been risen.
- *UnimplementedError*: Called a stub. Functionality has not yet been implemented.
- *ValueConversionError*: Error casting or converting a value.

14.7.1 Exception DimensionError

`mosek::fusion::DimensionError`

Thrown when a given object has the wrong number of dimensions, or they have not the right size.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.2 Exception DomainError

`mosek::fusion::DomainError`

Invalid domain.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.3 Exception ExpressionError

`mosek::fusion::ExpressionError`

Tried to construct an expression from invalid.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.4 Exception FatalError

`mosek::fusion::FatalError`

A fatal error has happened.

Implements *RuntimeException*

Members *RuntimeException.toString* – Return the exception message.

14.7.5 Exception FusionException

`mosek::fusion::FusionException`

Base class for all normal exceptions in fusion.

Implements *Exception*

Members *FusionException.toString* – Return the exception message.

Implemented by *SolutionError*

FusionException.toString

`string toString()`

Return the exception message.

Return (string)

14.7.6 Exception `FusionRuntimeException`

`mosek::fusion::FusionRuntimeException`

Base class for all run-time exceptions in fusion.

Implements `RuntimeException`

Members `FusionRuntimeException.toString` – Return the exception message.

Implemented by `ExpressionError`, `ValueConversionError`, `MatrixError`, `DomainError`, `DimensionError`, `OptimizeError`, `IndexError`, `LengthError`, `SetDefinitionError`, `ParameterError`, `SliceError`, `RangeError`, `IOError`, `SparseFormatError`, `NameError`, `ModelError`

`FusionRuntimeException.toString`

`string toString()`

Return the exception message.

Return (string)

14.7.7 Exception `IOError`

`mosek::fusion::IOError`

Error when reading or writing a stream, or opening a file.

Implements `FusionRuntimeException`

Members `FusionRuntimeException.toString` – Return the exception message.

14.7.8 Exception `IndexError`

`mosek::fusion::IndexError`

Index out of bound, or a multi-dimensional index had wrong number of dimensions.

Implements `FusionRuntimeException`

Members `FusionRuntimeException.toString` – Return the exception message.

14.7.9 Exception `LengthError`

`mosek::fusion::LengthError`

An array did not have the required length, or two arrays were expected to have same length.

Implements `FusionRuntimeException`

Members `FusionRuntimeException.toString` – Return the exception message.

14.7.10 Exception MatrixError

`mosek::fusion::MatrixError`

Thrown if data used in construction of a matrix contained inconsistencies or errors.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.11 Exception ModelError

`mosek::fusion::ModelError`

Thrown when objects from different models were mixed.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.12 Exception NameError

`mosek::fusion::NameError`

Name clash; tries to add a variable or constraint with a name that already exists.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.13 Exception OptimizeError

`mosek::fusion::OptimizeError`

An error occurred during optimization.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.14 Exception ParameterError

`mosek::fusion::ParameterError`

Tried to use an invalid parameter for a value that was invalid for a specific parameter.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.15 Exception RangeError

`mosek::fusion::RangeError`

Invalid range specified

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.16 Exception SetDefinitionError

`mosek::fusion::SetDefinitionError`

Invalid data for constructing set.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.17 Exception SliceError

`mosek::fusion::SliceError`

Invalid slice definition, negative slice or slice index out of bounds.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.18 Exception SolutionError

`mosek::fusion::SolutionError`

Requested a solution that was undefined or whose status was not acceptable.

Implements *FusionException*

Members *FusionException.toString* – Return the exception message.

14.7.19 Exception SparseFormatError

`mosek::fusion::SparseFormatError`

The given sparsity patterns was invalid or specified an index that was out of bounds.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.7.20 Exception UnexpectedError

`mosek::fusion::UnexpectedError`

An unexpected error has happened. No specific exception could have been risen.

Implements *RuntimeException*

Members *RuntimeException.toString* – Return the exception message.

14.7.21 Exception UnimplementedError

`mosek::fusion::UnimplementedError`

Called a stub. Functionality has not yet been implemented.

Implements *RuntimeException*

Members *RuntimeException.toString* – Return the exception message.

14.7.22 Exception ValueConversionError

`mosek::fusion::ValueConversionError`

Error casting or converting a value.

Implements *FusionRuntimeException*

Members *FusionRuntimeException.toString* – Return the exception message.

14.8 Class LinAlg

`mosek::LinAlg`

BLAS/LAPACK linear algebra routines.

Static members *LinAlg.axy* – Computes vector addition and multiplication by a scalar.

LinAlg.dot – Computes the inner product of two vectors.

LinAlg.gemm – Performs a dense matrix multiplication.

LinAlg.gemv – Computes dense matrix times a dense vector product.

LinAlg.potrf – Computes a Cholesky factorization of a dense matrix.

LinAlg.syeig – Computes all eigenvalues of a symmetric dense matrix.

LinAlg.syevd – Computes all the eigenvalues and eigenvectors of a symmetric dense matrix, and thus its eigenvalue decomposition.

LinAlg.syrk – Performs a rank-k update of a symmetric matrix.

`LinAlg.axy`

```
void LinAlg::axy(int n, double alpha, shared_ptr<ndarray<double,1>> x, shared_ptr<ndarray<double,1>> y)
```

Adds αx to y , i.e. performs the update

$$y := \alpha x + y.$$

Note that the result is stored overwriting y .

Parameters

- `n` (`int`) – Length of the vectors.
- `alpha` (`double`) – The scalar that multiplies x .
- `x` (`double[]`) – The x vector.
- `y` (`double[]`) – The y vector.

`LinAlg.dot`

```
double LinAlg::dot(int n, shared_ptr<ndarray<double,1>> x, shared_ptr<ndarray<double,1>> y)
```

Computes the inner product of two vectors x, y of length $n \geq 0$, i.e

$$x \cdot y = \sum_{i=1}^n x_i y_i.$$

Note that if $n = 0$, then the result of the operation is 0.

Parameters

- **n** (int) – Length of the vectors.
- **x** (double[]) – The x vector.
- **y** (double[]) – The y vector.

Return (double)

LinAlg.gemm

```
void LinAlg::gemm(mosek.transpose transa, mosek.transpose transb, int m, int n, int k,
↳double alpha, shared_ptr<ndarray<double,1>> a, shared_ptr<ndarray<double,1>> b, double
↳beta, shared_ptr<ndarray<double,1>> c)
```

Performs a matrix multiplication plus addition of dense matrices. Given A , B and C of compatible dimensions, this function computes

$$C := \alpha op(A)op(B) + \beta C$$

where α, β are two scalar values. The function $op(X)$ denotes X if `transX` is `NO`, or X^T if set to `YES`. The matrix C has m rows and n columns, and the other matrices must have compatible dimensions.

The result of this operation is stored in C .

Parameters

- **transa** (transpose) – Indicates if A should be transposed. See the Optimizer API documentation for the definition of these constants.
- **transb** (transpose) – Indicates if B should be transposed. See the Optimizer API documentation for the definition of these constants.
- **m** (int) – Indicates the number of rows of matrix C .
- **n** (int) – Indicates the number of columns of matrix C .
- **k** (int) – Specifies the common dimension along which $op(A)$ and $op(B)$ are multiplied. For example, if neither A nor B are transposed, then this is the number of columns in A and also the number of rows in B .
- **alpha** (double) – A scalar value multiplying the result of the matrix multiplication.
- **a** (double[]) – The pointer to the array storing matrix A in a column-major format.
- **b** (double[]) – The pointer to the array storing matrix B in a column-major format.
- **beta** (double) – A scalar value that multiplies C .
- **c** (double[]) – The pointer to the array storing matrix C in a column-major format.

LinAlg.gemv

```
void LinAlg::gemv(mosek.transpose trans, int m, int n, double alpha, shared_ptr<ndarray
↳<double,1>> a, shared_ptr<ndarray<double,1>> x, double beta, shared_ptr<ndarray<double,
↳1>> y)
```

Computes the multiplication of a scaled dense matrix times a dense vector, plus a scaled dense vector. Precisely, if `trans` is `NO` then the update is

$$y := \alpha Ax + \beta y,$$

and if `trans` is YES then

$$y := \alpha A^T x + \beta y,$$

where α, β are scalar values and A is a matrix with m rows and n columns.

Note that the result is stored overwriting y .

Parameters

- `trans` (`transpose`) – Indicates if A should be transposed. See the Optimizer API documentation for the definition of these constants.
- `m` (`int`) – Specifies the number of rows of the matrix A .
- `n` (`int`) – Specifies the number of columns of the matrix A .
- `alpha` (`double`) – A scalar value multiplying the matrix A .
- `a` (`double[]`) – A pointer to the array storing matrix A in a column-major format.
- `x` (`double[]`) – A pointer to the array storing the vector x .
- `beta` (`double`) – A scalar value multiplying the vector y .
- `y` (`double[]`) – A pointer to the array storing the vector y .

`LinAlg.potrf`

```
void LinAlg::potrf(mosek.uplo uplo, int n, shared_ptr<ndarray<double,1>> a)
```

Computes a Cholesky factorization of a real symmetric positive definite dense matrix.

Parameters

- `uplo` (`uplo`) – Indicates whether the upper or lower triangular part of the matrix is used. See the Optimizer API documentation for the definition of these constants.
- `n` (`int`) – Specifies the dimension of the symmetric matrix.
- `a` (`double[]`) – A symmetric matrix stored in column-major order. Only the lower or the upper triangular part is used, accordingly with the `uplo` argument. It will contain the result on exit.

`LinAlg.syeig`

```
void LinAlg::syeig(mosek.uplo uplo, int n, shared_ptr<ndarray<double,1>> a, shared_ptr<ndarray<double,1>> w)
```

Computes all eigenvalues of a real symmetric matrix A . Given a matrix $A \in \mathbb{R}^{n \times n}$ it returns a vector $w \in \mathbb{R}^n$ containing the eigenvalues of A .

Parameters

- `uplo` (`uplo`) – Indicates whether the upper or lower triangular part of the matrix is used. See the Optimizer API documentation for the definition of these constants.
- `n` (`int`) – Specifies the dimension of the symmetric matrix.
- `a` (`double[]`) – A symmetric matrix stored in column-major order. Only the lower or the upper triangular part is used, accordingly with the `uplo` argument. It will contain the result on exit.
- `w` (`double[]`) – Array of length at least `n` containing the eigenvalues of A .

LinAlg.syevd

```
void LinAlg::syevd(mosek.uplo uplo, int n, shared_ptr<ndarray<double,1>> a, shared_ptr<ndarray<double,1>> w)
```

Computes all the eigenvalues and eigenvectors a real symmetric matrix. Given the input matrix $A \in \mathbb{R}^{n \times n}$, this function returns a vector $w \in \mathbb{R}^n$ containing the eigenvalues of A and it also computes the eigenvectors of A . Therefore, this function computes the eigenvalue decomposition of A as

$$A = UVU^T,$$

where $V = \text{diag}(w)$ and U contains the eigenvectors of A .

Note that the matrix U overwrites the input data A .

Parameters

- **uplo** (`uplo`) – Indicates whether the upper or lower triangular part of the matrix is used. See the Optimizer API documentation for the definition of these constants.
- **n** (`int`) – Specifies the dimension of the symmetric matrix.
- **a** (`double[]`) – A symmetric matrix stored in column-major order. Only the lower or the upper triangular part is used, accordingly with the `uplo` argument. It will contain the result on exit.
- **w** (`double[]`) – Array of length at least `n` containing the eigenvalues of A .

LinAlg.syrk

```
void LinAlg::syrk(mosek.uplo uplo, mosek.transpose trans, int n, int k, double alpha, shared_ptr<ndarray<double,1>> a, double beta, shared_ptr<ndarray<double,1>> c)
```

Performs a symmetric rank- k update for a symmetric matrix.

Given a symmetric matrix $C \in \mathbb{R}^{n \times n}$, two scalars α, β and a matrix A of rank $k \leq n$, it computes either

$$C := \alpha AA^T + \beta C,$$

when `trans` is set to `NO` and $A \in \mathbb{R}^{n \times k}$, or

$$C := \alpha A^T A + \beta C,$$

when `trans` is set to `YES` and $A \in \mathbb{R}^{k \times n}$.

Only the part of C indicated by `uplo` is used and only that part is updated with the result.

Parameters

- **uplo** (`uplo`) – Indicates whether the upper or lower triangular part of C is used. See the Optimizer API documentation for the definition of these constants.
- **trans** (`transpose`) – Indicates if A should be transposed. See the Optimizer API documentation for the definition of these constants.
- **n** (`int`) – Specifies the order of C .
- **k** (`int`) – Indicates the number of rows or columns of A , depending on whether or not it is transposed, and its rank.
- **alpha** (`double`) – A scalar value multiplying the result of the matrix multiplication.

- **a** (`double[]`) – The pointer to the array storing matrix A in a column-major format.
- **beta** (`double`) – A scalar value that multiplies C .
- **c** (`double[]`) – The pointer to the array storing matrix C in a column-major format.

SUPPORTED FILE FORMATS

MOSEK supports a range of problem and solution formats listed in [Table 15.1](#) and [Table 15.2](#). The **Task format** is **MOSEK**'s native binary format and it supports all features that **MOSEK** supports. The **OPF format** is **MOSEK**'s human-readable alternative that supports nearly all features (everything except semidefinite problems). In general, text formats are significantly slower to read, but can be examined and edited directly in any text editor.

Problem formats

See [Table 15.1](#).

Table 15.1: List of supported file formats for optimization problems.

Format Type	Ext.	Binary/Text	LP	QO	CQO	SDP
<i>LP</i>	lp	plain text	X	X		
<i>MPS</i>	mps	plain text	X	X		
<i>OPF</i>	opf	plain text	X	X	X	
<i>CBF</i>	cbf	plain text	X		X	X
<i>OSiL</i>	xml	xml text	X	X		
<i>Task format</i>	task	binary	X	X	X	X
<i>Jtask format</i>	jtask	text	X	X	X	X

Solution formats

See [Table 15.2](#).

Table 15.2: List of supported solution formats.

Format Type	Ext.	Binary/Text	Description
<i>SOL</i>	sol	plain text	Interior Solution
	bas	plain text	Basic Solution
	int	plain text	Integer
<i>Jsol format</i>	jsol	text	Solution

Compression

MOSEK supports GZIP compression of files. Problem files with an additional `.gz` extension are assumed to be compressed when read, and are automatically compressed when written. For example, a file called

problem.mps.gz

will be considered as a GZIP compressed MPS file.

15.1 The LP File Format

MOSEK supports the LP file format with some extensions. The LP format is not a completely well-defined standard and hence different optimization packages may interpret the same LP file in slightly different ways. **MOSEK** tries to emulate as closely as possible CPLEX's behavior, but tries to stay backward compatible.

The LP file format can specify problems on the form

$$\begin{array}{ll} \text{minimize/maximize} & c^T x + \frac{1}{2} q^o(x) \\ \text{subject to} & \begin{array}{lll} l^c \leq & Ax + \frac{1}{2} q(x) & \leq u^c, \\ l^x \leq & x & \leq u^x, \\ & x_{\mathcal{J}} \text{ integer,} \end{array} \end{array}$$

where

- $x \in \mathbb{R}^n$ is the vector of decision variables.
- $c \in \mathbb{R}^n$ is the linear term in the objective.
- $q^o : \mathbb{R}^n \rightarrow \mathbb{R}$ is the quadratic term in the objective where

$$q^o(x) = x^T Q^o x$$

and it is assumed that

$$Q^o = (Q^o)^T.$$

- $A \in \mathbb{R}^{m \times n}$ is the constraint matrix.
- $l^c \in \mathbb{R}^m$ is the lower limit on the activity for the constraints.
- $u^c \in \mathbb{R}^m$ is the upper limit on the activity for the constraints.
- $l^x \in \mathbb{R}^n$ is the lower limit on the activity for the variables.
- $u^x \in \mathbb{R}^n$ is the upper limit on the activity for the variables.
- $q : \mathbb{R}^n \rightarrow \mathbb{R}$ is a vector of quadratic functions. Hence,

$$q_i(x) = x^T Q^i x$$

where it is assumed that

$$Q^i = (Q^i)^T.$$

- $\mathcal{J} \subseteq \{1, 2, \dots, n\}$ is an index set of the integer constrained variables.

15.1.1 File Sections

An LP formatted file contains a number of sections specifying the objective, constraints, variable bounds, and variable types. The section keywords may be any mix of upper and lower case letters.

Objective Function

The first section beginning with one of the keywords

```

max
maximum
maximize
min
minimum
minimize

```

defines the objective sense and the objective function, i.e.

$$c^T x + \frac{1}{2} x^T Q^o x.$$

The objective may be given a name by writing

```
myname:
```

before the expressions. If no name is given, then the objective is named `obj`.

The objective function contains linear and quadratic terms. The linear terms are written as:

```
4 x1 + x2 - 0.1 x3
```

and so forth. The quadratic terms are written in square brackets (`[]`) and are either squared or multiplied as in the examples

```
x1^2
```

and

```
x1 * x2
```

There may be zero or more pairs of brackets containing quadratic expressions.

An example of an objective section is

```

minimize
myobj: 4 x1 + x2 - 0.1 x3 + [ x1^2 + 2.1 x1 * x2 ]/2

```

Please note that the quadratic expressions are multiplied with $\frac{1}{2}$, so that the above expression means

$$\text{minimize } 4x_1 + x_2 - 0.1 \cdot x_3 + \frac{1}{2}(x_1^2 + 2.1 \cdot x_1 \cdot x_2)$$

If the same variable occurs more than once in the linear part, the coefficients are added, so that `4 x1 + 2 x1` is equivalent to `6 x1`. In the quadratic expressions `x1 * x2` is equivalent to `x2 * x1` and, as in the linear part, if the same variables multiplied or squared occur several times their coefficients are added.

Constraints

The second section beginning with one of the keywords

```

subj to
subject to
s.t.
st

```

defines the linear constraint matrix A and the quadratic matrices Q^i .

A constraint contains a name (optional), expressions adhering to the same rules as in the objective and a bound:

```

subject to
con1: x1 + x2 + [ x3^2 ]/2 <= 5.1

```

The bound type (here \leq) may be any of $<$, \leq , $=$, $>$, \geq ($<$ and \leq mean the same), and the bound may be any number.

In the standard LP format it is not possible to define more than one bound, but **MOSEK** supports defining ranged constraints by using double-colon ($::$) instead of a single-colon ($:$) after the constraint name, i.e.

$$-5 \leq x_1 + x_2 \leq 5 \quad (15.1)$$

may be written as

```
con:: -5 < x_1 + x_2 < 5
```

By default **MOSEK** writes ranged constraints this way.

If the files must adhere to the LP standard, ranged constraints must either be split into upper bounded and lower bounded constraints or be written as an equality with a slack variable. For example the expression (15.1) may be written as

$$x_1 + x_2 - sl_1 = 0, \quad -5 \leq sl_1 \leq 5.$$

Bounds

Bounds on the variables can be specified in the bound section beginning with one of the keywords

```
bound
bounds
```

The bounds section is optional but should, if present, follow the **subject to** section. All variables listed in the bounds section must occur in either the objective or a constraint.

The default lower and upper bounds are 0 and $+\infty$. A variable may be declared free with the keyword **free**, which means that the lower bound is $-\infty$ and the upper bound is $+\infty$. Furthermore it may be assigned a finite lower and upper bound. The bound definitions for a given variable may be written in one or two lines, and bounds can be any number or $\pm\infty$ (written as **+inf/-inf/+infinity/-infinity**) as in the example

```
bounds
x1 free
x2 <= 5
0.1 <= x2
x3 = 42
2 <= x4 < +inf
```

Variable Types

The final two sections are optional and must begin with one of the keywords

```
bin
binaries
binary
```

and

```
gen
general
```

Under **general** all integer variables are listed, and under **binary** all binary (integer variables with bounds 0 and 1) are listed:

```

general
x1 x2
binary
x3 x4

```

Again, all variables listed in the binary or general sections must occur in either the objective or a constraint.

Terminating Section

Finally, an LP formatted file must be terminated with the keyword

```
end
```

15.1.2 LP File Examples

Linear example lo1.lp

```

\ File: lo1.lp
maximize
obj: 3 x1 + x2 + 5 x3 + x4
subject to
c1: 3 x1 + x2 + 2 x3 = 30
c2: 2 x1 + x2 + 3 x3 + x4 >= 15
c3: 2 x2 + 3 x4 <= 25
bounds
0 <= x1 <= +infinity
0 <= x2 <= 10
0 <= x3 <= +infinity
0 <= x4 <= +infinity
end

```

Mixed integer example milo1.lp

```

maximize
obj: x1 + 6.4e-01 x2
subject to
c1: 5e+01 x1 + 3.1e+01 x2 <= 2.5e+02
c2: 3e+00 x1 - 2e+00 x2 >= -4e+00
bounds
0 <= x1 <= +infinity
0 <= x2 <= +infinity
general
x1 x2
end

```

15.1.3 LP Format peculiarities

Comments

Anything on a line after a \ is ignored and is treated as a comment.

Names

A name for an objective, a constraint or a variable may contain the letters *a-z*, *A-Z*, the digits *0-9* and the characters

!"#\$%&()/,.;?@_`'|~

The first character in a name must not be a number, a period or the letter *e* or *E*. Keywords must not be used as names.

MOSEK accepts any character as valid for names, except `\0`. A name that is not allowed in LP file will be changed and a warning will be issued.

The algorithm for making names LP valid works as follows: The name is interpreted as an **utf-8** string. For a unicode character *c*:

- If *c*==`_` (underscore), the output is `__` (two underscores).
- If *c* is a valid LP name character, the output is just *c*.
- If *c* is another character in the ASCII range, the output is `_XX`, where *XX* is the hexadecimal code for the character.
- If *c* is a character in the range *127-65535*, the output is `_uXXXX`, where *XXXX* is the hexadecimal code for the character.
- If *c* is a character above 65535, the output is `_UXXXXXXXX`, where *XXXXXXXX* is the hexadecimal code for the character.

Invalid **utf-8** substrings are escaped as `_XX'`, and if a name starts with a period, *e* or *E*, that character is escaped as `_XX`.

Variable Bounds

Specifying several upper or lower bounds on one variable is possible but **MOSEK** uses only the tightest bounds. If a variable is fixed (with `=`), then it is considered the tightest bound.

MOSEK Extensions to the LP Format

Some optimization software packages employ a more strict definition of the LP format than the one used by **MOSEK**. The limitations imposed by the strict LP format are the following:

- Quadratic terms in the constraints are not allowed.
- Names can be only 16 characters long.
- Lines must not exceed 255 characters in length.

To get around some of the inconveniences converting from other problem formats, **MOSEK** allows lines to contain 1024 characters and names may have any length (shorter than the 1024 characters).

15.1.4 Formatting of an LP File

A few parameters control the visual formatting of LP files written by **MOSEK** in order to make it easier to read the files. These parameters are

- *writeLpLineWidth*
- *writeLpTermsPerLine*

The first parameter sets the maximum number of characters on a single line. The default value is 80 corresponding roughly to the width of a standard text document.

The second parameter sets the maximum number of terms per line; a term means a sign, a coefficient, and a name (for example + 42 elephants). The default value is 0, meaning that there is no maximum.

Unnamed Constraints

Reading and writing an LP file with **MOSEK** may change it superficially. If an LP file contains unnamed constraints or objective these are given their generic names when the file is read (however unnamed constraints in **MOSEK** are written without names).

15.2 The MPS File Format

MOSEK supports the standard MPS format with some extensions. For a detailed description of the MPS format see the book by Nazareth [Naz87].

15.2.1 MPS File Structure

The version of the MPS format supported by **MOSEK** allows specification of an optimization problem of the form

$$\begin{aligned} l^c &\leq Ax + q(x) &&\leq u^c, \\ l^x &\leq x &&\leq u^x, \\ &x \in \mathcal{K}, \\ &x_{\mathcal{J}} \text{ integer}, \end{aligned} \tag{15.2}$$

where

- $x \in \mathbb{R}^n$ is the vector of decision variables.
- $A \in \mathbb{R}^{m \times n}$ is the constraint matrix.
- $l^c \in \mathbb{R}^m$ is the lower limit on the activity for the constraints.
- $u^c \in \mathbb{R}^m$ is the upper limit on the activity for the constraints.
- $l^x \in \mathbb{R}^n$ is the lower limit on the activity for the variables.
- $u^x \in \mathbb{R}^n$ is the upper limit on the activity for the variables.
- $q : \mathbb{R}^n \rightarrow \mathbb{R}$ is a vector of quadratic functions. Hence,

$$q_i(x) = \frac{1}{2} x^T Q^i x$$

where it is assumed that

$$Q^i = (Q^i)^T.$$

Please note the explicit $\frac{1}{2}$ in the quadratic term and that Q^i is required to be symmetric.

- \mathcal{K} is a convex cone.
- $\mathcal{J} \subseteq \{1, 2, \dots, n\}$ is an index set of the integer-constrained variables.

An MPS file with one row and one column can be illustrated like this:

```
*          1          2          3          4          5          6
*23456789012345678901234567890123456789012345678901234567890
NAME          [name]
OBJSENSE
[objsense]
OBJNAME
[objname]
ROWS
```

```

? [cname1]
COLUMNS
[vname1] [cname1] [value1] [vname3] [value2]
RHS
[name] [cname1] [value1] [cname2] [value2]
RANGES
[name] [cname1] [value1] [cname2] [value2]
QSECTION [cname1]
[vname1] [vname2] [value1] [vname3] [value2]
QMATRIX
[vname1] [vname2] [value1]
QUADOBJ
[vname1] [vname2] [value1]
QCMATRIX [cname1]
[vname1] [vname2] [value1]
BOUNDS
?? [name] [vname1] [value1]
CSECTION [kname1] [value1] [ktype]
[vname1]
ENDATA

```

Here the names in capitals are keywords of the MPS format and names in brackets are custom defined names or values. A couple of notes on the structure:

- Fields: All items surrounded by brackets appear in *fields*. The fields named “valueN” are numerical values. Hence, they must have the format

```
[+|-]XXXXXXX.XXXXXX[e|E] [+|-]XXX]
```

where

```
.. code-block:: text
```

```
X = [0|1|2|3|4|5|6|7|8|9].
```

- Sections: The MPS file consists of several sections where the names in capitals indicate the beginning of a new section. For example, COLUMNS denotes the beginning of the columns section.
- Comments: Lines starting with an * are comment lines and are ignored by **MOSEK**.
- Keys: The question marks represent keys to be specified later.
- Extensions: The sections QSECTION and CSECTION are specific **MOSEK** extensions of the MPS format. The sections QMATRIX, QUADOBJ and QCMATRIX are included for sake of compatibility with other vendors extensions to the MPS format.

The standard MPS format is a fixed format, i.e. everything in the MPS file must be within certain fixed positions. **MOSEK** also supports a *free format*. See [Sec. 15.2.9](#) for details.

Linear example lo1.mps

A concrete example of a MPS file is presented below:

```

* File: lo1.mps
NAME          lo1
OBJSENSE
    MAX
ROWS
    N  obj
    E  c1
    G  c2

```

```

L   c3
COLUMNS
  x1      obj      3
  x1      c1       3

  UP bound  x2      10
ENDATA

```

Subsequently each individual section in the MPS format is discussed.

Section NAME

In this section a name (`[name]`) is assigned to the problem.

OBJSENSE (optional)

This is an optional section that can be used to specify the sense of the objective function. The **OBJSENSE** section contains one line at most which can be one of the following

```

MIN
MINIMIZE
MAX
MAXIMIZE

```

It should be obvious what the implication is of each of these four lines.

OBJNAME (optional)

This is an optional section that can be used to specify the name of the row that is used as objective function. The **OBJNAME** section contains one line at most which has the form

```
objname
```

`objname` should be a valid row name.

ROWS

A record in the **ROWS** section has the form

```
? [cname1]
```

where the requirements for the fields are as follows:

Field	Starting Position	Max Width	required	Description
?	2	1	Yes	Constraint key
[cname1]	5	8	Yes	Constraint name

Hence, in this section each constraint is assigned an unique name denoted by [cname1]. Please note that [cname1] starts in position 5 and the field can be at most 8 characters wide. An initial key ? must be present to specify the type of the constraint. The key can have the values E, G, L, or N with the following interpretation:

Constraint type	l_i^c	u_i^c
E	finite	l_i^c
G	finite	∞
L	$-\infty$	finite
N	$-\infty$	∞

In the MPS format an objective vector is not specified explicitly, but one of the constraints having the key N will be used as the objective vector c . In general, if multiple N type constraints are specified, then the first will be used as the objective vector c .

COLUMNS

In this section the elements of A are specified using one or more records having the form:

[vname1]	[cname1]	[value1]	[cname2]	[value2]
----------	----------	----------	----------	----------

where the requirements for each field are as follows:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[cname1]	15	8	Yes	Constraint name
[value1]	25	12	Yes	Numerical value
[cname2]	40	8	No	Constraint name
[value2]	50	12	No	Numerical value

Hence, a record specifies one or two elements a_{ij} of A using the principle that [vname1] and [cname1] determines j and i respectively. Please note that [cname1] must be a constraint name specified in the ROWS section. Finally, [value1] denotes the numerical value of a_{ij} . Another optional element is specified by [cname2], and [value2] for the variable specified by [vname1]. Some important comments are:

- All elements belonging to one variable must be grouped together.
- Zero elements of A should not be specified.
- At least one element for each variable should be specified.

RHS (optional)

A record in this section has the format

[name]	[cname1]	[value1]	[cname2]	[value2]
--------	----------	----------	----------	----------

where the requirements for each field are as follows:

Field	Starting Position	Max Width	required	Description
[name]	5	8	Yes	Name of the RHS vector
[cname1]	15	8	Yes	Constraint name
[value1]	25	12	Yes	Numerical value
[cname2]	40	8	No	Constraint name
[value2]	50	12	No	Numerical value

The interpretation of a record is that [name] is the name of the RHS vector to be specified. In general, several vectors can be specified. [cname1] denotes a constraint name previously specified in the ROWS section. Now, assume that this name has been assigned to the i th constraint and v_1 denotes the value specified by [value1], then the interpretation of v_1 is:

Constraint	l_i^c	u_i^c
type		
E	v_1	v_1
G	v_1	
L		v_1
N		

An optional second element is specified by [cname2] and [value2] and is interpreted in the same way. Please note that it is not necessary to specify zero elements, because elements are assumed to be zero.

RANGES (optional)

A record in this section has the form

[name]	[cname1]	[value1]	[cname2]	[value2]
--------	----------	----------	----------	----------

where the requirements for each fields are as follows:

Field	Starting Position	Max Width	required	Description
[name]	5	8	Yes	Name of the RANGE vector
[cname1]	15	8	Yes	Constraint name
[value1]	25	12	Yes	Numerical value
[cname2]	40	8	No	Constraint name
[value2]	50	12	No	Numerical value

The records in this section are used to modify the bound vectors for the constraints, i.e. the values in l^c and u^c . A record has the following interpretation: [name] is the name of the RANGE vector and [cname1] is a valid constraint name. Assume that [cname1] is assigned to the i th constraint and let v_1 be the value specified by [value1], then a record has the interpretation:

Constraint type	Sign of v_1	l_i^c	u_i^c
E	−	$u_i^c + v_1$	
E	+		$l_i^c + v_1$
G	− or +	$l_i^c + v_1 $	
L	− or +	$u_i^c - v_1 $	
N			

QSECTION (optional)

Within the QSECTION the label [cname1] must be a constraint name previously specified in the ROWS section. The label [cname1] denotes the constraint to which the quadratic term belongs. A record in the QSECTION has the form

[vname1]	[vname2]	[value1]	[vname3]	[value2]
----------	----------	----------	----------	----------

where the requirements for each field are:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[vname2]	15	8	Yes	Variable name
[value1]	25	12	Yes	Numerical value
[vname3]	40	8	No	Variable name
[value2]	50	12	No	Numerical value

A record specifies one or two elements in the lower triangular part of the Q^i matrix where [cname1] specifies the i . Hence, if the names [vname1] and [vname2] have been assigned to the k th and j th variable, then Q_{kj}^i is assigned the value given by [value1]. An optional second element is specified in the same way by the fields [vname1], [vname3], and [value2].

The example

$$\begin{array}{ll} \text{minimize} & -x_2 + \frac{1}{2}(2x_1^2 - 2x_1x_3 + 0.2x_2^2 + 2x_3^2) \\ \text{subject to} & x_1 + x_2 + x_3 \geq 1, \\ & x \geq 0 \end{array}$$

has the following MPS file representation

```
* File: qo1.mps
NAME          qo1
ROWS
N  obj
G  c1
COLUMNS
x1      c1      1.0
x2      obj     -1.0
x2      c1      1.0
x3      c1      1.0
RHS
rhs      c1      1.0
QSECTION      obj
x1      x1      2.0
x1      x3     -1.0
x2      x2      0.2
x3      x3      2.0
ENDATA
```

Regarding the QSECTIONs please note that:

- Only one QSECTION is allowed for each constraint.
- The QSECTIONs can appear in an arbitrary order after the COLUMNS section.
- All variable names occurring in the QSECTION must already be specified in the COLUMNS section.
- All entries specified in a QSECTION are assumed to belong to the lower triangular part of the quadratic term of Q .

QMATRIX/QUADOBJ (optional)

The QMATRIX and QUADOBJ sections allow to define the quadratic term of the objective function. They differ in how the quadratic term of the objective function is stored:

- QMATRIX It stores all the nonzeros coefficients, without taking advantage of the symmetry of the Q matrix.

- **QUADOBJ** It only store the upper diagonal nonzero elements of the Q matrix.

A record in both sections has the form:

[vname1]	[vname2]	[value1]
----------	----------	----------

where the requirements for each field are:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[vname2]	15	8	Yes	Variable name
[value1]	25	12	Yes	Numerical value

A record specifies one elements of the Q matrix in the objective function . Hence, if the names [vname1] and [vname2] have been assigned to the k th and j th variable, then Q_{kj} is assigned the value given by [value1]. Note that a line must apper for each off-diagonal coefficient if using a **QMATRIX** section, while only one entry is required in a **QUADOBJ** section. The quadratic part of the objective function will be evaluated as $1/2x^T Qx$.

The example

$$\begin{aligned} \text{minimize} \quad & -x_2 + \frac{1}{2}(2x_1^2 - 2x_1x_3 + 0.2x_2^2 + 2x_3^2) \\ \text{subject to} \quad & x_1 + x_2 + x_3 \geq 1, \\ & x \geq 0 \end{aligned}$$

has the following MPS file representation using **QMATRIX**

```
* File: qo1_matrix.mps
NAME          qo1_qmatrix
ROWS
  N  obj
  G  c1
COLUMNS
  x1      c1      1.0
  x2      obj     -1.0
  x2      c1      1.0
  x3      c1      1.0
RHS
  rhs     c1      1.0
QMATRIX
  x1      x1      2.0
  x1      x3     -1.0
  x3      x1     -1.0
  x2      x2      0.2
  x3      x3      2.0
ENDATA
```

or the following using **QUADOBJ**

```
* File: qo1_quadobj.mps
NAME          qo1_quadobj
ROWS
  N  obj
  G  c1
COLUMNS
  x1      c1      1.0
  x2      obj     -1.0
  x2      c1      1.0
  x3      c1      1.0
RHS
  rhs     c1      1.0
QUADOBJ
```

```

x1      x1      2.0
x1      x3     -1.0
x2      x2      0.2
x3      x3      2.0
ENDATA

```

Please also note that:

- A QMATRIX/QUADOBJ section can appear in an arbitrary order after the COLUMNS section.
- All variable names occurring in the QMATRIX/QUADOBJ section must already be specified in the COLUMNS section.

15.2.2 QCMATRIX (optional)

A QCMATRIX section allows to specify the quadratic part of a given constraints. Within the QCMATRIX the label [cname1] must be a constraint name previously specified in the ROWS section. The label [cname1] denotes the constraint to which the quadratic term belongs. A record in the QSECTION has the form

```
[vname1] [vname2] [value1]
```

where the requirements for each field are:

Field	Starting Position	Max Width	required	Description
[vname1]	5	8	Yes	Variable name
[vname2]	15	8	Yes	Variable name
[value1]	25	12	Yes	Numerical value

A record specifies an entry of the Q^i matrix where [cname1] specifies the i . Hence, if the names [vname1] and [vname2] have been assigned to the k th and j th variable, then Q_{kj}^i is assigned the value given by [value1]. Moreover, the quadratic term is represented as $1/2x^T Qx$.

The example

$$\begin{aligned}
 &\text{minimize} && x_2 \\
 &\text{subject to} && x_1 + x_2 + x_3 \geq 1, \\
 & && \frac{1}{2}(-2x_1x_3 + 0.2x_2^2 + 2x_3^2) \leq 10, \\
 & && x \geq 0
 \end{aligned}$$

has the following MPS file representation

```

* File: qo1.mps
NAME          qo1
ROWS
  N  obj
  G  c1
  L  q1
COLUMNS
  x1      c1      1.0
  x2      obj     -1.0
  x2      c1      1.0
  x3      c1      1.0
RHS
  rhs     c1      1.0
  rhs     q1     10.0
QCMATRIX  q1
  x1      x1      2.0
  x1      x3     -1.0
  x3      x1     -1.0
  x2      x2      0.2

```

x3	x3	2.0
ENDATA		

Regarding the QCMATRIXs please note that:

- Only one QCMATRIX is allowed for each constraint.
- The QCMATRIXs can appear in an arbitrary order after the COLUMNS section.
- All variable names occurring in the QSECTION must already be specified in the COLUMNS section.
- A QCMATRIX does not exploit the symmetry of Q : an off-diagonal entry (i, j) should appear twice.

15.2.3 BOUNDS (optional)

In the BOUNDS section changes to the default bounds vectors l^x and u^x are specified. The default bounds vectors are $l^x = 0$ and $u^x = \infty$. Moreover, it is possible to specify several sets of bound vectors. A record in this section has the form

??	[name]	[vname1]	[value1]
----	--------	----------	----------

where the requirements for each field are:

Field	Starting Position	Max Width	Required	Description
??	2	2	Yes	Bound key
[name]	5	8	Yes	Name of the BOUNDS vector
[vname1]	15	8	Yes	Variable name
[value1]	25	12	No	Numerical value

Hence, a record in the BOUNDS section has the following interpretation: [name] is the name of the bound vector and [vname1] is the name of the variable which bounds are modified by the record. ?? and [value1] are used to modify the bound vectors according to the following table:

??	l_j^x	u_j^x	Made integer (added to \mathcal{J})
FR	$-\infty$	∞	No
FX	v_1	v_1	No
LO	v_1	unchanged	No
MI	$-\infty$	unchanged	No
PL	unchanged	∞	No
UP	unchanged	v_1	No
BV	0	1	Yes
LI	$\lceil v_1 \rceil$	unchanged	Yes
UI	unchanged	$\lfloor v_1 \rfloor$	Yes

v_1 is the value specified by [value1].

15.2.4 CSECTION (optional)

The purpose of the CSECTION is to specify the constraint

$$x \in \mathcal{K}.$$

in (15.2). It is assumed that \mathcal{K} satisfies the following requirements. Let

$$x^t \in \mathbb{R}^{n^t}, \quad t = 1, \dots, k$$

be vectors comprised of parts of the decision variables x so that each decision variable is a member of exactly **one** vector x^t , for example

$$x^1 = \begin{bmatrix} x_1 \\ x_4 \\ x_7 \end{bmatrix} \quad \text{and} \quad x^2 = \begin{bmatrix} x_6 \\ x_5 \\ x_3 \\ x_2 \end{bmatrix}.$$

Next define

$$\mathcal{K} := \{x \in \mathbb{R}^n : x^t \in \mathcal{K}_t, \quad t = 1, \dots, k\}$$

where \mathcal{K}_t must have one of the following forms

- \mathbb{R} set:

$$\mathcal{K}_t = \{x \in \mathbb{R}^{n^t}\}.$$

- Quadratic cone:

$$\mathcal{K}_t = \left\{ x \in \mathbb{R}^{n^t} : x_1 \geq \sqrt{\sum_{j=2}^{n^t} x_j^2} \right\}. \quad (15.3)$$

- Rotated quadratic cone:

$$\mathcal{K}_t = \left\{ x \in \mathbb{R}^{n^t} : 2x_1x_2 \geq \sum_{j=3}^{n^t} x_j^2, \quad x_1, x_2 \geq 0 \right\}. \quad (15.4)$$

In general, only quadratic and rotated quadratic cones are specified in the MPS file whereas membership of the \mathbb{R} set is not. If a variable is not a member of any other cone then it is assumed to be a member of an \mathbb{R} cone.

Next, let us study an example. Assume that the quadratic cone

$$x_4 \geq \sqrt{x_5^2 + x_8^2}$$

and the rotated quadratic cone

$$x_3x_7 \geq x_1^2 + x_0^2, \quad x_3, x_7 \geq 0,$$

should be specified in the MPS file. One **CSECTION** is required for each cone and they are specified as follows:

*	1	2	3	4	5	6
*2345678901234567890123456789012345678901234567890						
CSECTION	konea	0.0	QUAD			
x4						
x5						
x8						
CSECTION	koneb	0.0	RQUAD			
x7						
x3						
x1						
x0						

This first CSECTION specifies the cone (15.3) which is given the name `konea`. This is a quadratic cone which is specified by the keyword `QUAD` in the CSECTION header. The 0.0 value in the CSECTION header is not used by the `QUAD` cone.

The second CSECTION specifies the rotated quadratic cone (15.4). Please note the keyword `RQUAD` in the CSECTION which is used to specify that the cone is a rotated quadratic cone instead of a quadratic cone. The 0.0 value in the CSECTION header is not used by the `RQUAD` cone.

In general, a CSECTION header has the format

CSECTION	[kname1]	[value1]	[ktype]
----------	----------	----------	---------

where the requirement for each field are as follows:

Field	Starting Position	Max Width	Required	Description
[kname1]	5	8	Yes	Name of the cone
[value1]	15	12	No	Cone parameter
[ktype]	25		Yes	Type of the cone.

The possible cone type keys are:

Cone type key	Members	Interpretation.
QUAD	≤ 1	Quadratic cone i.e. (15.3).
RQUAD	≤ 2	Rotated quadratic cone i.e. (15.4).

Please note that a quadratic cone must have at least one member whereas a rotated quadratic cone must have at least two members. A record in the CSECTION has the format

[vname1]

where the requirements for each field are

Field	Starting Position	Max Width	required	Description
[vname1]	2	8	Yes	A valid variable name

The most important restriction with respect to the CSECTION is that a variable must occur in only one CSECTION.

15.2.5 ENDATA

This keyword denotes the end of the MPS file.

15.2.6 Integer Variables

Using special bound keys in the BOUNDS section it is possible to specify that some or all of the variables should be integer-constrained i.e. be members of \mathcal{J} . However, an alternative method is available.

This method is available only for backward compatibility and we recommend that it is not used. This method requires that markers are placed in the COLUMNS section as in the example:

COLUMNS				
x1	obj	-10.0	c1	0.7
x1	c2	0.5	c3	1.0
x1	c4	0.1		
* Start of integer-constrained variables.				
MARK000	'MARKER'		'INTORG'	
x2	obj	-9.0	c1	1.0

x2	c2	0.8333333333	c3	0.66666667
x2	c4	0.25		
x3	obj	1.0	c6	2.0
MARK001	'MARKER'		'INTEND'	

- End of integer-constrained variables.

Please note that special marker lines are used to indicate the start and the end of the integer variables. Furthermore be aware of the following

- **IMPORTANT:** All variables between the markers are assigned a default lower bound of 0 and a default upper bound of 1. **This may not be what is intended.** If it is not intended, the correct bounds should be defined in the **BOUNDS** section of the MPS formatted file.
- **MOSEK** ignores field 1, i.e. **MARK0001** and **MARK001**, however, other optimization systems require them.
- Field 2, i.e. **MARKER**, must be specified including the single quotes. This implies that no row can be assigned the name **MARKER**.
- Field 3 is ignored and should be left blank.
- Field 4, i.e. **INTORG** and **INTEND**, must be specified.
- It is possible to specify several such integer marker sections within the **COLUMNS** section.

15.2.7 General Limitations

- An MPS file should be an ASCII file.

15.2.8 Interpretation of the MPS Format

Several issues related to the MPS format are not well-defined by the industry standard. However, **MOSEK** uses the following interpretation:

- If a matrix element in the **COLUMNS** section is specified multiple times, then the multiple entries are added together.
- If a matrix element in a **QSECTION** section is specified multiple times, then the multiple entries are added together.

15.2.9 The Free MPS Format

MOSEK supports a free format variation of the MPS format. The free format is similar to the MPS file format but less restrictive, e.g. it allows longer names. However, it also presents two main limitations:

- A name must not contain any blanks.

15.3 The OPF Format

The *Optimization Problem Format (OPF)* is an alternative to LP and MPS files for specifying optimization problems. It is row-oriented, inspired by the CPLEX LP format.

Apart from containing objective, constraints, bounds etc. it may contain complete or partial solutions, comments and extra information relevant for solving the problem. It is designed to be easily read and modified by hand and to be forward compatible with possible future extensions.

Intended use

The OPF file format is meant to replace several other files:

- The LP file format: Any problem that can be written as an LP file can be written as an OPF file too; furthermore it naturally accommodates ranged constraints and variables as well as arbitrary characters in names, fixed expressions in the objective, empty constraints, and conic constraints.
- Parameter files: It is possible to specify integer, double and string parameters along with the problem (or in a separate OPF file).
- Solution files: It is possible to store a full or a partial solution in an OPF file and later reload it.

15.3.1 The File Format

The format uses tags to structure data. A simple example with the basic sections may look like this:

```
[comment]
This is a comment. You may write almost anything here...
[/comment]

# This is a single-line comment.

[objective min 'myobj']
x + 3 y + x^2 + 3 y^2 + z + 1
[/objective]

[constraints]
[con 'con01'] 4 <= x + y  [/con]
[/constraints]

[bounds]
[b] -10 <= x,y <= 10  [/b]

[cone quad] x,y,z [/cone]
[/bounds]
```

A scope is opened by a tag of the form `[tag]` and closed by a tag of the form `[/tag]`. An opening tag may accept a list of unnamed and named arguments, for examples:

```
[tag value] tag with one unnamed argument [/tag]
[tag arg=value] tag with one named argument in quotes [/tag]
```

Unnamed arguments are identified by their order, while named arguments may appear in any order, but never before an unnamed argument. The `value` can be a quoted, single-quoted or double-quoted text string, i.e.

```
[tag 'value']      single-quoted value [/tag]
[tag arg='value']  single-quoted value [/tag]
[tag "value"]      double-quoted value [/tag]
[tag arg="value"]  double-quoted value [/tag]
```

Sections

The recognized tags are

[comment]

A comment section. This can contain *almost* any text: Between single quotes (') or double quotes (") any text may appear. Outside quotes the markup characters ([and]) must be prefixed by backslashes. Both single and double quotes may appear alone or inside a pair of quotes if it is prefixed by a backslash.

[objective]

The objective function: This accepts one or two parameters, where the first one (in the above example `min`) is either `min` or `max` (regardless of case) and defines the objective sense, and the second one (above `myobj`), if present, is the objective name. The section may contain linear and quadratic expressions. If several objectives are specified, all but the last are ignored.

[constraints]

This does not directly contain any data, but may contain the subsection `con` defining a linear constraint.

[`con`] defines a single constraint; if an argument is present ([`con NAME`]) this is used as the name of the constraint, otherwise it is given a null-name. The section contains a constraint definition written as linear and quadratic expressions with a lower bound, an upper bound, with both or with an equality. Examples:

```
[constraints]
[con 'con1'] 0 <= x + y      [/con]
[con 'con2'] 0 >= x + y      [/con]
[con 'con3'] 0 <= x + y <= 10 [/con]
[con 'con4']      x + y = 10 [/con]
[/constraints]
```

Constraint names are unique. If a constraint is specified which has the same name as a previously defined constraint, the new constraint replaces the existing one.

[bounds]

This does not directly contain any data, but may contain the subsections `b` (linear bounds on variables) and `cone` (quadratic cone).

[`b`]. Bound definition on one or several variables separated by comma (,). An upper or lower bound on a variable replaces any earlier defined bound on that variable. If only one bound (upper or lower) is given only this bound is replaced. This means that upper and lower bounds can be specified separately. So the OPF bound definition:

```
[b] x,y >= -10 [/b]
[b] x,y <= 10  [/b]
```

results in the bound $-10 \leq x, y \leq 10$.

[`cone`]. currently supports the *quadratic cone* and the *rotated quadratic cone*.

A conic constraint is defined as a set of variables which belong to a single unique cone.

- A quadratic cone of n variables x_1, \dots, x_n defines a constraint of the form

$$x_1^2 \geq \sum_{i=2}^n x_i^2, \quad x_1 \geq 0.$$

- A rotated quadratic cone of n variables x_1, \dots, x_n defines a constraint of the form

$$2x_1x_2 \geq \sum_{i=3}^n x_i^2, \quad x_1, x_2 \geq 0.$$

A `[bounds]`-section example:

```
[bounds]
[b] 0 <= x,y <= 10 [/b] # ranged bound
[b] 10 >= x,y >= 0 [/b] # ranged bound
[b] 0 <= x,y <= inf [/b] # using inf
[b]      x,y free [/b] # free variables
# Let (x,y,z,w) belong to the cone K
[cone quad] x,y,z,w [/cone] # quadratic cone
[cone rquad] x,y,z,w [/cone] # rotated quadratic cone
[/bounds]
```

By default all variables are free.

`[variables]`

This defines an ordering of variables as they should appear in the problem. This is simply a space-separated list of variable names. Optionally, an attribute can be added `[variables disallow_new_variables]` indicating that if any variable not listed here occurs later in the file it is an error.

`[integer]`

This contains a space-separated list of variables and defines the constraint that the listed variables must be integer values.

`[hints]`

This may contain only non-essential data; for example estimates of the number of variables, constraints and non-zeros. Placed before all other sections containing data this may reduce the time spent reading the file.

In the `hints` section, any subsection which is not recognized by **MOSEK** is simply ignored. In this section a hint in a subsection is defined as follows:

```
[hint ITEM] value [/hint]
```

where `ITEM` may be replaced by `numvar` (number of variables), `numcon` (number of linear/quadratic constraints), `numanz` (number of linear non-zeros in constraints) and `numqnz` (number of quadratic non-zeros in constraints).

`[solutions]`

This section can contain a set of full or partial solutions to a problem. Each solution must be specified using a `[solution]`-section, i.e.

```
[solutions]
[solution]...[/solution] #solution 1
[solution]...[/solution] #solution 2
#other solutions....
[solution]...[/solution] #solution n
[/solutions]
```

Note that a `[solution]`-section must be always specified inside a `[solutions]`-section. The syntax of a `[solution]`-section is the following:

`[solution SOLTYPE status=STATUS]...[/solution]`

where `SOLTYPE` is one of the strings

- `interior`, a non-basic solution,
- `basic`, a basic solution,
- `integer`, an integer solution,

and `STATUS` is one of the strings

- `UNKNOWN`,
- `OPTIMAL`,
- `INTEGER_OPTIMAL`,
- `PRIM_FEAS`,
- `DUAL_FEAS`,
- `PRIM_AND_DUAL_FEAS`,
- `NEAR_OPTIMAL`,
- `NEAR_PRIM_FEAS`,
- `NEAR_DUAL_FEAS`,
- `NEAR_PRIM_AND_DUAL_FEAS`,
- `PRIM_INFEAS_CER`,
- `DUAL_INFEAS_CER`,
- `NEAR_PRIM_INFEAS_CER`,
- `NEAR_DUAL_INFEAS_CER`,
- `NEAR_INTEGER_OPTIMAL`.

Most of these values are irrelevant for input solutions; when constructing a solution for simplex hot-start or an initial solution for a mixed integer problem the safe setting is `UNKNOWN`.

A `[solution]`-section contains `[con]` and `[var]` sections. Each `[con]` and `[var]` section defines solution information for a single variable or constraint, specified as list of `KEYWORD/value` pairs, in any order, written as

`KEYWORD=value`

Allowed keywords are as follows:

- `sk`. The status of the item, where the `value` is one of the following strings:
 - `LOW`, the item is on its lower bound.
 - `UPR`, the item is on its upper bound.
 - `FIX`, it is a fixed item.
 - `BAS`, the item is in the basis.
 - `SUPBAS`, the item is super basic.
 - `UNK`, the status is unknown.
 - `INF`, the item is outside its bounds (infeasible).
- `lv1` Defines the level of the item.

- **sl** Defines the level of the dual variable associated with its lower bound.
- **su** Defines the level of the dual variable associated with its upper bound.
- **sn** Defines the level of the variable associated with its cone.
- **y** Defines the level of the corresponding dual variable (for constraints only).

A **[var]** section should always contain the items **sk**, **lvl**, **sl** and **su**. Items **sl** and **su** are not required for **integer** solutions.

A **[con]** section should always contain **sk**, **lvl**, **sl**, **su** and **y**.

An example of a solution section

```
[solution basic status=UNKNOWN]
[var x0] sk=LOW    lvl=5.0    [/var]
[var x1] sk=UPR    lvl=10.0   [/var]
[var x2] sk=SUPBAS lvl=2.0    sl=1.5 su=0.0 [/var]

[con c0] sk=LOW    lvl=3.0 y=0.0 [/con]
[con c0] sk=UPR    lvl=0.0 y=5.0 [/con]
[/solution]
```

- **[vendor]** This contains solver/vendor specific data. It accepts one argument, which is a vendor ID – for **MOSEK** the ID is simply **mosek** – and the section contains the subsection **parameters** defining solver parameters. When reading a vendor section, any unknown vendor can be safely ignored. This is described later.

Comments using the **#** may appear anywhere in the file. Between the **#** and the following line-break any text may be written, including markup characters.

Numbers

Numbers, when used for parameter values or coefficients, are written in the usual way by the **printf** function. That is, they may be prefixed by a sign (+ or -) and may contain an integer part, decimal part and an exponent. The decimal point is always . (a dot). Some examples are

```
1
1.0
.0
1.
1e10
1e+10
1e-10
```

Some *invalid* examples are

```
e10    # invalid, must contain either integer or decimal part
.       # invalid
.e10   # invalid
```

More formally, the following standard regular expression describes numbers as used:

```
[+|-]?([0-9]+[.][0-9]*|.[0-9]+)([eE][+|-]?[0-9]+)?
```

Names

Variable names, constraint names and objective name may contain arbitrary characters, which in some cases must be enclosed by quotes (single or double) that in turn must be preceded by a backslash. Unquoted names must begin with a letter (**a-z** or **A-Z**) and contain only the following characters: the letters **a-z** and **A-Z**, the digits **0-9**, braces (**{** and **}**) and underscore (**_**).

Some examples of legal names:

```
an_unquoted_name
another_name{123}
'single quoted name'
"double quoted name"
"name with \"quote\" in it"
"name with []s in it"
```

15.3.2 Parameters Section

In the `vendor` section solver parameters are defined inside the `parameters` subsection. Each parameter is written as

```
[p PARAMETER_NAME] value [/p]
```

where `PARAMETER_NAME` is replaced by a **MOSEK** parameter name, usually of the form `MSK_IPAR_...`, `MSK_DPAR_...` or `MSK_SPAR_...`, and the `value` is replaced by the value of that parameter; both integer values and named values may be used. Some simple examples are

```
[vendor mosek]
[parameters]
[p MSK_IPAR_OPF_MAX_TERMS_PER_LINE] 10      [/p]
[p MSK_IPAR_OPF_WRITE_PARAMETERS]    MSK_ON [/p]
[p MSK_DPAR_DATA_TOL_BOUND_INF]      1.0e18 [/p]
[/parameters]
[/vendor]
```

15.3.3 Writing OPF Files from MOSEK

To write an OPF file add the `.opf` extension to the file name.

15.3.4 Examples

This section contains a set of small examples written in OPF and describing how to formulate linear, quadratic and conic problems.

Linear Example `lo1.opf`

Consider the example:

$$\begin{array}{llllll} \text{maximize} & 3x_0 & + & 1x_1 & + & 5x_2 & + & 1x_3 \\ \text{subject to} & 3x_0 & + & 1x_1 & + & 2x_2 & & = & 30, \\ & 2x_0 & + & 1x_1 & + & 3x_2 & + & 1x_3 & \geq & 15, \\ & & & 2x_1 & & & + & 3x_3 & \leq & 25, \end{array}$$

having the bounds

$$\begin{array}{llll} 0 & \leq & x_0 & \leq & \infty, \\ 0 & \leq & x_1 & \leq & 10, \\ 0 & \leq & x_2 & \leq & \infty, \\ 0 & \leq & x_3 & \leq & \infty. \end{array}$$

In the OPF format the example is displayed as shown in [Listing 15.1](#).

Listing 15.1: Example of an OPF file for a linear problem.

```

[comment]
  The lo1 example in OPF format
[/comment]

[hints]
  [hint NUMVAR] 4 [/hint]
  [hint NUMCON] 3 [/hint]
  [hint NUMANZ] 9 [/hint]
[/hints]

[variables disallow_new_variables]
  x1 x2 x3 x4
[/variables]

[objective maximize 'obj']
  3 x1 + x2 + 5 x3 + x4
[/objective]

[constraints]
  [con 'c1'] 3 x1 +   x2 + 2 x3           = 30 [/con]
  [con 'c2'] 2 x1 +   x2 + 3 x3 +   x4 >= 15 [/con]
  [con 'c3']      2 x2           + 3 x4 <= 25 [/con]
[/constraints]

[bounds]
  [b] 0 <= * [/b]
  [b] 0 <= x2 <= 10 [/b]
[/bounds]

```

Quadratic Example qo1.opf

An example of a quadratic optimization problem is

$$\begin{aligned}
 &\text{minimize} && x_1^2 + 0.1x_2^2 + x_3^2 - x_1x_3 - x_2 \\
 &\text{subject to} && 1 \leq x_1 + x_2 + x_3, \\
 &&& x \geq 0.
 \end{aligned}$$

This can be formulated in opf as shown below.

Listing 15.2: Example of an OPF file for a quadratic problem.

```

[comment]
  The qo1 example in OPF format
[/comment]

[hints]
  [hint NUMVAR] 3 [/hint]
  [hint NUMCON] 1 [/hint]
  [hint NUMANZ] 3 [/hint]
  [hint NUMQNZ] 4 [/hint]
[/hints]

[variables disallow_new_variables]
  x1 x2 x3
[/variables]

[objective minimize 'obj']
  # The quadratic terms are often written with a factor of 1/2 as here,
  # but this is not required.

```

```
- x2 + 0.5 ( 2.0 x1 ^ 2 - 2.0 x3 * x1 + 0.2 x2 ^ 2 + 2.0 x3 ^ 2 )
[/objective]

[constraints]
[con 'c1'] 1.0 <= x1 + x2 + x3 [/con]
[/constraints]

[bounds]
[b] 0 <= * [/b]
[/bounds]
```

Conic Quadratic Example cqo1.opf

Consider the example:

$$\begin{aligned} &\text{minimize} && x_3 + x_4 + x_5 \\ &\text{subject to} && x_0 + x_1 + 2x_2 = 1, \\ & && x_0, x_1, x_2 \geq 0, \\ & && x_3 \geq \sqrt{x_0^2 + x_1^2}, \\ & && 2x_4x_5 \geq x_2^2. \end{aligned}$$

Please note that the type of the cones is defined by the parameter to `[cone ...]`; the content of the `cone`-section is the names of variables that belong to the cone. The resulting OPF file is in [Listing 15.3](#).

Listing 15.3: Example of an OPF file for a conic quadratic problem.

```
[comment]
The cqo1 example in OPF format.
[/comment]

[hints]

[hint NUMCON] 1 [/hint]
[hint NUMANZ] 3 [/hint]
[/hints]

[variables disallow_new_variables]
x1 x2 x3 x4 x5 x6
[/variables]

[objective minimize 'obj']
x4 + x5 + x6
[/objective]

[constraints]
[con 'c1'] x1 + x2 + 2e+00 x3 = 1e+00 [/con]
[/constraints]

[bounds]
# We let all variables default to the positive orthant
[b] 0 <= * [/b]

# ...and change those that differ from the default
[b] x4,x5,x6 free [/b]

# Define quadratic cone: x4 >= sqrt( x1^2 + x2^2 )
[cone quad 'k1'] x4, x1, x2 [/cone]

# Define rotated quadratic cone: 2 x5 x6 >= x3^2
```

```
[cone rquad 'k2'] x5, x6, x3 [/cone]
[/bounds]
```

Mixed Integer Example milo1.opf

Consider the mixed integer problem:

$$\begin{aligned} & \text{maximize} && x_0 + 0.64x_1 \\ & \text{subject to} && 50x_0 + 31x_1 \leq 250, \\ & && 3x_0 - 2x_1 \geq -4, \\ & && x_0, x_1 \geq 0 \quad \text{and integer} \end{aligned}$$

This can be implemented in OPF with the file in [Listing 15.4](#).

Listing 15.4: Example of an OPF file for a mixed-integer linear problem.

```
[comment]

  x1 x2
[/variables]

[objective maximize 'obj']
  x1 + 6.4e-1 x2
[/objective]

[constraints]
  [con 'c1'] 5e+1 x1 + 3.1e+1 x2 <= 2.5e+2 [/con]
  [con 'c2'] -4 <= 3 x1 - 2 x2 [/con]
[/constraints]

[bounds]
  [b] 0 <= * [/b]
[/bounds]

[integer]
  x1 x2
[/integer]
```

15.4 The CBF Format

This document constitutes the technical reference manual of the *Conic Benchmark Format* with file extension: `.cbf` or `.CBF`. It unifies linear, second-order cone (also known as conic quadratic) and semidefinite optimization with mixed-integer variables. The format has been designed with benchmark libraries in mind, and therefore focuses on compact and easily parsable representations. The problem structure is separated from the problem data, and the format moreover facilitates benchmarking of hotstart capability through sequences of changes.

15.4.1 How Instances Are Specified

This section defines the spectrum of conic optimization problems that can be formulated in terms of the keywords of the CBF format.

In the CBF format, conic optimization problems are considered in the following form:

$$\begin{aligned}
 & \min / \max && g^{obj} \\
 & \text{s.t.} && \begin{aligned} & g_i \in \mathcal{K}_i, & i \in \mathcal{I}, \\ & G_i \in \mathcal{K}_i, & i \in \mathcal{I}^{PSD}, \\ & x_j \in \mathcal{K}_j, & j \in \mathcal{J}, \\ & \overline{X}_j \in \mathcal{K}_j, & j \in \mathcal{J}^{PSD}. \end{aligned}
 \end{aligned} \tag{15.5}$$

- **Variables** are either scalar variables, x_j for $j \in \mathcal{J}$, or variables, \overline{X}_j for $j \in \mathcal{J}^{PSD}$. Scalar variables can also be declared as integer.
- **Constraints** are affine expressions of the variables, either scalar-valued g_i for $i \in \mathcal{I}$, or matrix-valued G_i for $i \in \mathcal{I}^{PSD}$

$$\begin{aligned}
 g_i &= \sum_{j \in \mathcal{J}^{PSD}} \langle F_{ij}, X_j \rangle + \sum_{j \in \mathcal{J}} a_{ij} x_j + b_i, \\
 G_i &= \sum_{j \in \mathcal{J}} x_j H_{ij} + D_i.
 \end{aligned}$$

- The **objective function** is a scalar-valued affine expression of the variables, either to be minimized or maximized. We refer to this expression as g^{obj}

$$g^{obj} = \sum_{j \in \mathcal{J}^{PSD}} \langle F_j^{obj}, X_j \rangle + \sum_{j \in \mathcal{J}} a_j^{obj} x_j + b^{obj}.$$

CBF format can represent the following cones \mathcal{K} :

- **Free domain** - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n\}, \text{ for } n \geq 1.$$

- **Positive orthant** - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n \mid x_j \geq 0 \text{ for } j = 1, \dots, n\}, \text{ for } n \geq 1.$$

- **Negative orthant** - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n \mid x_j \leq 0 \text{ for } j = 1, \dots, n\}, \text{ for } n \geq 1.$$

- **Fixpoint zero** - A cone in the linear family defined by

$$\{x \in \mathbb{R}^n \mid x_j = 0 \text{ for } j = 1, \dots, n\}, \text{ for } n \geq 1.$$

- **Quadratic cone** - A cone in the second-order cone family defined by

$$\left\{ \begin{pmatrix} p \\ x \end{pmatrix} \in \mathbb{R} \times \mathbb{R}^{n-1}, p^2 \geq x^T x, p \geq 0 \right\}, \text{ for } n \geq 2.$$

- **Rotated quadratic cone** - A cone in the second-order cone family defined by

$$\left\{ \begin{pmatrix} p \\ q \\ x \end{pmatrix} \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n-2}, 2pq \geq x^T x, p \geq 0, q \geq 0 \right\}, \text{ for } n \geq 3.$$

15.4.2 The Structure of CBF Files

This section defines how information is written in the CBF format, without being specific about the type of information being communicated.

All information items belong to exactly one of the three groups of information. These information groups, and the order they must appear in, are:

1. File format.
2. Problem structure.
3. Problem data.

The first group, file format, provides information on how to interpret the file. The second group, problem structure, provides the information needed to deduce the type and size of the problem instance. Finally, the third group, problem data, specifies the coefficients and constants of the problem instance.

Information items

The format is composed as a list of information items. The first line of an information item is the **KEYWORD**, revealing the type of information provided. The second line - of some keywords only - is the **HEADER**, typically revealing the size of information that follows. The remaining lines are the **BODY** holding the actual information to be specified.

KEYWORD BODY KEYWORD HEADER BODY
--

The **KEYWORD** determines how each line in the **HEADER** and **BODY** is structured. Moreover, the number of lines in the **BODY** follows either from the **KEYWORD**, the **HEADER**, or from another information item required to precede it.

Embedded hotstart-sequences

A sequence of problem instances, based on the same problem structure, is within a single file. This is facilitated via the **CHANGE** within the problem data information group, as a separator between the information items of each instance. The information items following a **CHANGE** keyword are appending to, or changing (e.g., setting coefficients back to their default value of zero), the problem data of the preceding instance.

The sequence is intended for benchmarking of hotstart capability, where the solvers can reuse their internal state and solution (subject to the achieved accuracy) as warmpoint for the succeeding instance. Whenever this feature is unsupported or undesired, the keyword **CHANGE** should be interpreted as the end of file.

File encoding and line width restrictions

The format is based on the US-ASCII printable character set with two extensions as listed below. Note, by definition, that none of these extensions can be misinterpreted as printable US-ASCII characters:

- A line feed marks the end of a line, carriage returns are ignored.
- Comment-lines may contain unicode characters in UTF-8 encoding.

The line width is restricted to 512 bytes, with 3 bytes reserved for the potential carriage return, line feed and null-terminator.

Integers and floating point numbers must follow the ISO C decimal string representation in the standard C locale. The format does not impose restrictions on the magnitude of, or number of significant digits in numeric data, but the use of 64-bit integers and 64-bit IEEE 754 floating point numbers should be sufficient to avoid loss of precision.

Comment-line and whitespace rules

The format allows single-line comments respecting the following rule:

- Lines having first byte equal to '#' (US-ASCII 35) are comments, and should be ignored. Comments are only allowed between information items.

Given that a line is not a comment-line, whitespace characters should be handled according to the following rules:

- Leading and trailing whitespace characters should be ignored.
 - The separator between multiple pieces of information on one line, is either one or more whitespace characters.
- Lines containing only whitespace characters are empty, and should be ignored. Empty lines are only allowed between information items.

15.4.3 Problem Specification

The problem structure

The problem structure defines the objective sense, whether it is minimization and maximization. It also defines the index sets, \mathcal{J} , \mathcal{J}^{PSD} , \mathcal{I} and \mathcal{I}^{PSD} , which are all numbered from zero, $\{0, 1, \dots\}$, and empty until explicitly constructed.

- **Scalar variables** are constructed in vectors restricted to a conic domain, such as $(x_0, x_1) \in \mathbb{R}_+^2$, $(x_2, x_3, x_4) \in \mathcal{Q}^3$, etc. In terms of the Cartesian product, this generalizes to

$$x \in \mathcal{K}_1^{n_1} \times \mathcal{K}_2^{n_2} \times \dots \times \mathcal{K}_k^{n_k}$$

which in the CBF format becomes:

```
VAR
n k
K1 n1
K2 n2
...
Kk nk
```

where $\sum_i n_i = n$ is the total number of scalar variables. The list of supported cones is found in [Table 15.3](#). Integrality of scalar variables can be specified afterwards.

- **PSD variables** are constructed one-by-one. That is, $X_j \succeq \mathbf{0}^{n_j \times n_j}$ for $j \in \mathcal{J}^{PSD}$, constructs a matrix-valued variable of size $n_j \times n_j$ restricted to be symmetric positive semidefinite. In the CBF format, this list of constructions becomes:

```
PSDVAR
N
n1
n2
...
nN
```

where N is the total number of PSD variables.

- **Scalar constraints** are constructed in vectors restricted to a conic domain, such as $(g_0, g_1) \in \mathbb{R}_+^2$, $(g_2, g_3, g_4) \in \mathcal{Q}^3$, etc. In terms of the Cartesian product, this generalizes to

$$g \in \mathcal{K}_1^{m_1} \times \mathcal{K}_2^{m_2} \times \dots \times \mathcal{K}_k^{m_k}$$

which in the CBF format becomes:

```
CON
m k
K1 m1
K2 m2
..
Kk mk
```

where $\sum_i m_i = m$ is the total number of scalar constraints. The list of supported cones is found in [Table 15.3](#).

- **PSD constraints** are constructed one-by-one. That is, $G_i \succeq \mathbf{0}^{m_i \times m_i}$ for $i \in \mathcal{I}^{PSD}$, constructs a matrix-valued affine expressions of size $m_i \times m_i$ restricted to be symmetric positive semidefinite. In the CBF format, this list of constructions becomes

```
PSDCON
M
m1
m2
..
mM
```

where M is the total number of PSD constraints.

With the objective sense, variables (with integer indications) and constraints, the definitions of the many affine expressions follow in problem data.

Problem data

The problem data defines the coefficients and constants of the affine expressions of the problem instance. These are considered zero until explicitly defined, implying that instances with no keywords from this information group are, in fact, valid. Duplicating or conflicting information is a failure to comply with the standard. Consequently, two coefficients written to the same position in a matrix (or to transposed positions in a symmetric matrix) is an error.

The affine expressions of the objective, g^{obj} , of the scalar constraints, g_i , and of the PSD constraints, G_i , are defined separately. The following notation uses the standard trace inner product for matrices, $\langle X, Y \rangle = \sum_{i,j} X_{ij} Y_{ij}$.

- The affine expression of the objective is defined as

$$g^{obj} = \sum_{j \in \mathcal{J}^{PSD}} \langle F_j^{obj}, X_j \rangle + \sum_{j \in \mathcal{J}} a_j^{obj} x_j + b^{obj},$$

in terms of the symmetric matrices, F_j^{obj} , and scalars, a_j^{obj} and b_j^{obj} .

- The affine expressions of the scalar constraints are defined, for $i \in \mathcal{I}$, as

$$g_i = \sum_{j \in \mathcal{J}^{PSD}} \langle F_{ij}, X_j \rangle + \sum_{j \in \mathcal{J}} a_{ij} x_j + b_i,$$

in terms of the symmetric matrices, F_{ij} , and scalars, a_{ij} and b_i .

- The affine expressions of the PSD constraints are defined, for $i \in \mathcal{I}^{PSD}$, as

$$G_i = \sum_{j \in \mathcal{J}} x_j H_{ij} + D_i,$$

in terms of the symmetric matrices, H_{ij} and D_i .

List of cones

The format uses an explicit syntax for symmetric positive semidefinite cones as shown above. For scalar variables and constraints, constructed in vectors, the supported conic domains and their minimum sizes are given as follows.

Table 15.3: Cones available in the CBF format

Name	CBF keyword	Cone family
Free domain	F	linear
Positive orthant	L+	linear
Negative orthant	L-	linear
Fixpoint zero	L=	linear
Quadratic cone	Q	second-order
Rotated quadratic cone	QR	second-order

15.4.4 File Format Keywords

VER

Description: The version of the Conic Benchmark Format used to write the file.

HEADER: None

BODY: One line formatted as:

INT

This is the version number.

Must appear exactly once in a file, as the first keyword.

OBJSENSE

Description: Define the objective sense.

HEADER: None

BODY: One line formatted as:

STR

having MIN indicates minimize, and MAX indicates maximize. Capital letters are required.

Must appear exactly once in a file.

PSDVAR

Description: Construct the PSD variables.

HEADER: One line formatted as:

INT

This is the number of PSD variables in the problem.

BODY: A list of lines formatted as:

INT

This indicates the number of rows (equal to the number of columns) in the matrix-valued PSD variable. The number of lines should match the number stated in the header.

VAR

Description: Construct the scalar variables.

HEADER: One line formatted as:

INT INT

This is the number of scalar variables, followed by the number of conic domains they are restricted to.

BODY: A list of lines formatted as:

STR INT

This indicates the cone name (see [Table 15.3](#)), and the number of scalar variables restricted to this cone. These numbers should add up to the number of scalar variables stated first in the header. The number of lines should match the second number stated in the header.

INT

Description: Declare integer requirements on a selected subset of scalar variables.

HEADER: one line formatted as:

INT

This is the number of integer scalar variables in the problem.

BODY: a list of lines formatted as:

INT

This indicates the scalar variable index $j \in \mathcal{J}$. The number of lines should match the number stated in the header.

Can only be used after the keyword **VAR**.

PSDCON

Description: Construct the PSD constraints.

HEADER: One line formatted as:

INT

This is the number of PSD constraints in the problem.

BODY: A list of lines formatted as:

INT

This indicates the number of rows (equal to the number of columns) in the matrix-valued affine expression of the PSD constraint. The number of lines should match the number stated in the header.

Can only be used after these keywords: PSDVAR, VAR.

CON

Description: Construct the scalar constraints.

HEADER: One line formatted as:

INT INT

This is the number of scalar constraints, followed by the number of conic domains they restrict to.

BODY: A list of lines formatted as:

STR INT

This indicates the cone name (see [Table 15.3](#)), and the number of affine expressions restricted to this cone. These numbers should add up to the number of scalar constraints stated first in the header. The number of lines should match the second number stated in the header.

Can only be used after these keywords: PSDVAR, VAR

OBJFCOORD

Description: Input sparse coordinates (quadruplets) to define the symmetric matrices F_j^{obj} , as used in the objective.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT INT INT REAL

This indicates the PSD variable index $j \in \mathcal{J}^{PSD}$, the row index, the column index and the coefficient value. The number of lines should match the number stated in the header.

OBJACOORD

Description: Input sparse coordinates (pairs) to define the scalars, a_j^{obj} , as used in the objective.

HEADER: One line formatted as:

INT

This is the number of coordinates to be specified.

BODY: A list of lines formatted as:

INT REAL

15.4.5 CBF Format Examples

Minimal Working Example

The conic optimization problem (15.6), has three variables in a quadratic cone - first one is integer - and an affine expression in domain 0 (equality constraint).

$$\begin{aligned} &\text{minimize} && 5.1 x_0 \\ &\text{subject to} && 6.2 x_1 + 7.3 x_2 - 8.4 \in \{0\} \\ &&& x \in \mathcal{Q}^3, x_0 \in \mathbb{Z}. \end{aligned} \tag{15.6}$$

Its formulation in the Conic Benchmark Format begins with the version of the CBF format used, to safeguard against later revisions.

```
VER
1
```

Next follows the problem structure, consisting of the objective sense, the number and domain of variables, the indices of integer variables, and the number and domain of scalar-valued affine expressions (i.e., the equality constraint).

```
OBJSENSE
MIN

VAR
3 1
Q 3

INT
1
0

CON
1 1
L= 1
```

Finally follows the problem data, consisting of the coefficients of the objective, the coefficients of the constraints, and the constant terms of the constraints. All data is specified on a sparse coordinate form.

```

0 -8.4
```

This concludes the example.

Mixing Linear, Second-order and Semidefinite Cones

The conic optimization problem (15.7), has a semidefinite cone, a quadratic cone over unordered subindices, and two equality constraints.

$$\begin{aligned}
 & \text{minimize} && \left\langle \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}, X_1 \right\rangle + x_1 \\
 & \text{subject to} && \left\langle \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, X_1 \right\rangle + x_1 &= 1.0, \\
 & && \left\langle \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, X_1 \right\rangle + x_0 + x_2 &= 0.5, \\
 & && x_1 \geq \sqrt{x_0^2 + x_2^2}, \\
 & && X_1 \succeq \mathbf{0}.
 \end{aligned} \tag{15.7}$$

The equality constraints are easily rewritten to the conic form, $(g_0, g_1) \in \{0\}^2$, by moving constants such that the right-hand-side becomes zero. The quadratic cone does not fit under the `VAR` keyword in this variable permutation. Instead, it takes a scalar constraint $(g_2, g_3, g_4) = (x_1, x_0, x_2) \in \mathcal{Q}^3$, with scalar variables constructed as $(x_0, x_1, x_2) \in \mathbb{R}^3$. Its formulation in the CBF format is reported in the following list

```

Mixing Semidefinite Variables and Linear Matrix Inequalities

The standard forms in semidefinite optimization are usually based either on semidefinite variables or linear matrix inequalities. In the CBF format, both forms are supported and can even be mixed as shown in.

$$\begin{aligned}
 & \text{minimize} && \left\langle \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, X_1 \right\rangle + x_1 + x_2 + 1 \\
 & \text{subject to} && \left\langle \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, X_1 \right\rangle - x_1 - x_2 \geq 0.0, \\
 & && x_1 \begin{bmatrix} 0 & 1 \\ 1 & 3 \end{bmatrix} + x_2 \begin{bmatrix} 3 & 1 \\ 1 & 0 \end{bmatrix} - \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \succeq \mathbf{0}, \\
 & && X_1 \succeq \mathbf{0}.
 \end{aligned} \tag{15.8}$$

Its formulation in the CBF format is written in what follows

```

Optimization Over a Sequence of Objectives

The linear optimization problem (15.9), is defined for a sequence of objectives such that hotstarting from one to the next might be advantages.

$$\begin{aligned}
 & \text{maximize}_k && g_k^{obj} \\
 & \text{subject to} && 50x_0 + 31 \leq 250, \\
 & && 3x_0 - 2x_1 \geq -4, \\
 & && x \in \mathbb{R}_+^2,
 \end{aligned} \tag{15.9}$$

given,

1. $g_0^{obj} = x_0 + 0.64x_1$.
2. $g_1^{obj} = 1.11x_0 + 0.76x_1$.
3. $g_2^{obj} = 1.11x_0 + 0.85x_1$.

Its formulation in the CBF format is reported in [Listing 15.5](#).

15.5 The XML (OSiL) Format

MOSEK can write data in the standard OSiL xml format. For a definition of the OSiL format please see <http://www.optimizationservices.org/>.

Only linear constraints (possibly with integer variables) are supported. By default output files with the extension `.xml` are written in the OSiL format.

15.6 The Task Format

The Task format is **MOSEK**'s native binary format. It contains a complete image of a **MOSEK** task, i.e.

- Problem data: Linear, conic quadratic, semidefinite and quadratic data
- Problem item names: Variable names, constraints names, cone names etc.
- Parameter settings
- Solutions

There are a few things to be aware of:

- The task format *does not* support General Convex problems since these are defined by arbitrary user-defined functions.
- Status of a solution read from a file will *always* be unknown.
- Parameter settings in a task file *always override* any parameters set on the command line or in a parameter file.

The format is based on the *TAR* (USTar) file format. This means that the individual pieces of data in a `.task` file can be examined by unpacking it as a *TAR* file. Please note that the inverse may not work: Creating a file using *TAR* will most probably not create a valid **MOSEK** Task file since the order of the entries is important.

15.7 The JSON Format

MOSEK provides the possibility to read/write problems in valid JSON format.

JSON (JavaScript Object Notation) is a lightweight data-interchange format. It is easy for humans to read and write. It is easy for machines to parse and generate. It is based on a subset of the JavaScript Programming Language, Standard ECMA-262 3rd Edition - December 1999. JSON is a text format that is completely language independent but uses conventions that are familiar to programmers of the C-family of languages, including C, C++, C#, Java, JavaScript, Perl, Python, and many others. These properties make JSON an ideal data-interchange language.

The official JSON website <http://www.json.org> provides plenty of information along with the format definition.

MOSEK defines two JSON-like formats:

- *jtask*
- *jsol*

Warning: Despite being text-based human-readable formats, *jtask* and *jsol* files will include no indentation and no new-lines, in order to keep the files as compact as possible. We therefore strongly advise to use JSON viewer tools to inspect *jtask* and *jsol* files.

15.7.1 *jtask* format

It stores a problem instance. The *jtask* format contains the same information as a *task format*.

Even though a *jtask* file is human-readable, we do not recommend users to create it by hand, but to rely on MOSEK.

15.7.2 *jsol* format

It stores a problem solution. The *jsol* format contains all solutions and information items.

15.7.3 A *jtask* example

In Listing 15.6 we present a file in the *jtask* format that corresponds to the sample problem from `lo1.lp`. The listing has been formatted for readability.

Listing 15.6: A formatted *jtask* file for the `lo1.lp` example.

15.8 The Solution File Format

MOSEK provides several solution files depending on the problem type and the optimizer used:

- *basis solution file* (extension `.bas`) if the problem is optimized using the simplex optimizer or basis identification is performed,
- *interior solution file* (extension `.sol`) if a problem is optimized using the interior-point optimizer and no basis identification is required,
- *integer solution file* (extension `.int`) if the problem contains integer constrained variables.

All solution files have the format:

NAME	: <problem name>							
PROBLEM STATUS	: <status of the problem>							
SOLUTION STATUS	: <status of the solution>							
OBJECTIVE NAME	: <name of the objective function>							
PRIMAL OBJECTIVE	: <primal objective value corresponding to the solution>							
DUAL OBJECTIVE	: <dual objective value corresponding to the solution>							
CONSTRAINTS								
INDEX	NAME	AT	ACTIVITY	LOWER LIMIT	UPPER LIMIT	DUAL LOWER	DUAL UPPER	
?	<name>	??	<a value>	<a value>	<a value>	<a value>	<a value>	
VARIABLES								
INDEX	NAME	AT	ACTIVITY	LOWER LIMIT	UPPER LIMIT	DUAL LOWER	DUAL UPPER	CONIC
↔DUAL								
?	<name>	??	<a value>	<a value>	<a value>	<a value>	<a value>	<a value>

In the example the fields ? and <> will be filled with problem and solution specific information. As can be observed a solution report consists of three sections, i.e.

- **HEADER** In this section, first the name of the problem is listed and afterwards the problem and solution status are shown. Next the primal and dual objective values are displayed.
- **CONSTRAINTS** For each constraint i of the form

$$l_i^c \leq \sum_{j=1}^n a_{ij}x_j \leq u_i^c, \quad (15.10)$$

the following information is listed:

- **INDEX:** A sequential index assigned to the constraint by **MOSEK**
- **NAME:** The name of the constraint assigned by the user.
- **AT:** The status of the constraint. In Table 15.4 the possible values of the status keys and their interpretation are shown.

Table 15.4: Status keys.

Status key	Interpretation
UN	Unknown status
BS	Is basic
SB	Is superbasic
LL	Is at the lower limit (bound)
UL	Is at the upper limit (bound)
EQ	Lower limit is identical to upper limit
**	Is infeasible i.e. the lower limit is greater than the upper limit.

- **ACTIVITY:** the quantity $\sum_{j=1}^n a_{ij}x_j^*$, where x^* is the value of the primal solution.
- **LOWER LIMIT:** the quantity l_i^c (see (15.10).)
- **UPPER LIMIT:** the quantity u_i^c (see (15.10).)
- **DUAL LOWER:** the dual multiplier corresponding to the lower limit on the constraint.
- **DUAL UPPER:** the dual multiplier corresponding to the upper limit on the constraint.

- **VARIABLES** The last section of the solution report lists information about the variables. This information has a similar interpretation as for the constraints. However, the column with the header CONIC DUAL is included for problems having one or more conic constraints. This column shows the dual variables corresponding to the conic constraints.

Example: `lo1.sol`

In [Listing 15.7](#) we show the solution file for the `lo1.opf` problem.

Listing 15.7: An example of `.sol` file.

```

LIST OF EXAMPLES

List of examples shipped in the distribution of Fusion API for C++:

Table 16.1: List of distributed examples

File	Description
<code>TrafficNetworkModel.cc</code>	Demonstrates a traffic network problem as a conic quadratic problem (CQO)
<code>alan.cc</code>	A portfolio choice model <code>alan.gms</code> from the GAMS model library
<code>baker.cc</code>	A small bakery revenue maximization linear problem
<code>breaksolver.cc</code>	Shows how to break a long-running task
<code>callback.cc</code>	An example of data/progress callback
<code>cqo1.cc</code>	A simple conic quadratic problem
<code>diet.cc</code>	Solving Stigler's Nutrition model <code>diet</code> from the GAMS model library
<code>duality.cc</code>	Shows how to access the dual solution
<code>facility_location.cc</code>	Demonstrates a small one-facility location problem (CQO)
<code>lo1.cc</code>	A simple linear problem
<code>lowerjohn_ellipsoids.cc</code>	Computes the Lower-John inner and outer ellipsoidal approximations of a polytope (SDO, CQO)
<code>lpt.cc</code>	Demonstrates how to solve the multi-processor scheduling problem and input an integer feasible point (MIP)
<code>milo1.cc</code>	A simple mixed-integer linear problem
<code>miointsol.cc</code>	A simple mixed-integer linear problem with an initial guess
<code>nearestcorr.cc</code>	Solves the nearest correlation matrix problem (SDO, CQO)
<code>parameters.cc</code>	Shows how to set optimizer parameters and read information items
<code>portfolio.cc</code>	Presents several portfolio optimization models
<code>primal_svm.cc</code>	Implements a simple soft-margin Support Vector Machine (CQO)
<code>production.cc</code>	Demonstrate how to modify and re-optimize a linear problem
<code>qcqp_sdo_relaxation.cc</code>	Demonstrate how to use SDP to solve convex relaxation of a mixed-integer QCQO problem
<code>sdo1.cc</code>	A simple semidefinite optimization problem
<code>sospoly.cc</code>	Models the cone of nonnegative polynomials and nonnegative trigonometric polynomials using Nesterov's framework
<code>sudoku.cc</code>	A SUDOKU solver (MIP)
<code>total_variation.cc</code>	Demonstrates how to solve a total variation problem (CQO)
<code>tsp.cc</code>	Solves a simple Travelling Salesman Problem and shows how to add constraints to a model and re-optimize (MIP)

Additional examples can be found on the **MOSEK** website and in other **MOSEK** publications.

INTERFACE CHANGES

The section show interface-specific changes to the **MOSEK** Fusion API for C++ in version 8. See the [release notes](#) for general changes and new features of the **MOSEK** Optimization Suite.

17.1 Compatibility

Fusion API has undergo a deep refactorization that will most likely make old code fail to compile. On a general level:

- more linear operators are available,
- pretty printing is implemented for most classes,
- variable operators (such slicingm stacking,...) are now moved to a specific class *Var*, pretty much like expressions have their own *Expr*.
- dimensions can now be expressed directly with arrays instead of the *Set* class
- reduced need for explicit conversion from variable to expression, i.e. the *Variable.asExpr*,
- new syntax to specify integer variables, as well as a short-hand for binary ones.

17.2 Parameters

Added

- *intpntQoTolDfeas*
- *intpntQoTolInfeas*
- *intpntQoTolMuRed*
- *intpntQoTolNearRel*
- *intpntQoTolPfeas*
